Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Description**BACKGROUND OF THE INVENTION:**5 **I. Field of the Invention**

The present invention relates to an apparatus for controlling steering of wheels of a vehicle and, more particularly, to an apparatus for controlling steering of wheels of a vehicle in which a high correction capability of variables representing vehicle behaviors is provided against disturbance such as side and gusty
10 winds, and high response for changes in vehicle behaviors in response to a steering input such as rapid steering or vehicle turning with a large radius.

II. Description of the Prior Art

15 Traveling performance and steering stability of a vehicle primarily depend on a yaw rate (i.e., angular velocity generated around the center of gravity when the vehicle is viewed from the top) of the vehicle responding to a steering input, i.e., a steering wheel operation, or a lateral acceleration (i.e., an acceleration acting on the center of gravity of the vehicle in a direction perpendicular to the vehicle traveling direction, i.e., an acceleration parallel to the traveling direction of the vehicle).

20 It is an ideal to guarantee safety for causing the vehicle to travel straight according to the will of a driver without being influenced by disturbance such as a side wind or a road surface friction coefficient when the vehicle is to quickly respond to the steering input or is to be driven straight.

In order to provide both dynamic characteristics and stability described above, Japanese Laid-Open Patent Publication 60-161266 corresponding to EP-A- 0 150 857 describes an apparatus obtained by combining feed forward control and feedback control. In this apparatus, the following two methods are used.
25 The first method is to control traveling performance and stability by a value obtained such that a differential value of a difference obtained by subtracting a coefficient multiple of a yaw rate or a lateral acceleration from a steering wheel angle is added to the difference, as shown in Fig. 2. The second method is practiced as follows, as shown in Fig. 3. A value is obtained by multiplying a coefficient with a differential value of a
30 steering wheel angle and is added to the steering angle to obtain a sum. The sum is used as a feed forward signal for auxiliary steering of the rear wheels, and the vehicle behaviors are used as a negative feedback signal for auxiliary steering of the front wheels. The drawback of feedback control is canceled with that of feedback control.

In the auxiliary steering apparatus described above, when a driver rapidly turns the steering wheel in order to detour an obstacle, auxiliary variables representing vehicle behaviors are rapidly increased by a
35 control value influenced by the differential value, and the vehicle is rapidly turned. Heavy mental load imposed on the driver is caused by rapid vehicle turning. In the worst case, the driver excessively turns the steering wheel, the vehicle loses stability, and a traffic accident may occur. When the vehicle travels along a curved road having a relatively large radius (e.g., a highway), the differential value is rarely influenced on
40 the vehicle behaviors. The feed forward signal is decreased, and understeering in the vehicle is caused as a whole. As a result, traveling performance of the vehicle is degraded. When an external force acts on the vehicle due to a side wind, ruts, or steps, the driver tends to turn the steering wheel with a guess so as to respond to accidental disturbances. Such steering increases the differential value, and oversteering may be caused to lead to unexpected vehicle behaviors.

45 The above disadvantage of the conventional auxiliary steering apparatus is caused by feed forward control using a steering wheel angle and a value obtained by multiplying a differential value of the steering wheel angle with a coefficient. The influence of the differential value is increased as compared with the normal steering apparatus, and desired control cannot be performed. When the coefficient multiplied with the differential value is decreased, a total gain is reduced and the control system in the vehicle is substantially
50 the same as that of feedback control. Optimal control cannot be performed by the above-mentioned auxiliary steering apparatus.

In the auxiliary steering apparatus shown in Fig. 3, independent control operations are performed for the front and rear wheels. Behaviors of the front and rear wheels are independently performed and the required control apparatus is complicated, thus increasing the overall weight and the like of the vehicle and
55 hence failing to obtain the desired control effect.

SUMMARY OF THE INVENTION:

It is an object of the present invention to achieve optimal steering wherein a steering system is controlled to provide a high behavior correction capacity for a side wind or disturbance and to shorten the response time for vehicle behavior changes responding to a steering input.

It is another object of the present invention to cause a steering control system having a high behavior correction capacity for a side wind or disturbance and a short response time for vehicle behavior changes responding to a steering input to perform optimal steering corresponding to changes in inside and outside environmental situations associated with the vehicle.

The disadvantage of the prior art is based on simple use of two values, i.e., the steering wheel angle and the value obtained by multiplying the coefficient with the differential value of the steering wheel angle in feed forward control. In order to eliminate this disadvantage, the present inventors also took values as coefficient multiples of the steering wheel angle into consideration in addition to the above-mentioned two values in feed forward control. The present inventors found that a combination of feed forward control and feedback control provided better travelling performance and stability.

When the driver rapidly turns the steering wheel, rapid changes in vehicle behaviors are restricted by values of coefficient multiples of the steering wheel angle in addition to use of the differential value of the steering wheel angle in order to prevent a rapid change in vehicle traveling direction. The metal load imposed on the driver can be reduced and hence the vehicle can be safely driven. The vehicle wheels are quickly responded at only the initial period upon turning of the steering wheel.

Understeering of the vehicle can be reduced by the values of coefficient multiples of the steering wheel angle when the vehicle is turning with a large radius. Stability in feed forward control can be assured without degrading dynamic characteristics of the vehicle. Auxiliary vehicle steering having high resistance to disturbance and a short response time can be achieved.

When the driver turns the steering wheel with a guess against an external force such as a side or gusty wind blown against the vehicle, the influence of the differential value can be suppressed by the coefficient multiple of the steering wheel angle. As a result, stable traveling can be achieved.

In the prior art described above, response to the changes in a friction value (μ) between the road surface and the vehicle wheels is insufficient. The present inventors paid attention to realization of optimal steering corresponding to changes in inside and outside environmental situations associated with the vehicle by changing coefficients (gains) of coefficient circuits in feedback and/or feed forward control system in accordance with a change in friction value μ between the road surface and the vehicle wheels and by determining coefficients of the coefficient circuits on the basis of friction value μ estimated by the vehicle travel state variables with the vehicle travel behaviors.

Even if the vehicle wheels do not slip on the road, the steering control system can be operated to suppress changes in vehicle behaviors. For example, magnitudes of signals for state variables representing vehicle behaviors are compared with respect to the steering angles in the rough and smooth road surfaces. Friction values μ are estimated by the above comparison operations, and the gains of the yaw rate feedback system are controlled using the estimated friction values. The changes in vehicle behaviors such as the yaw rate can be therefore decreased. In addition, by detecting road surface conditions, even if a large noise component tends to be mixed in state variables as in a rough road or when operation failure of sensors occurs, the gains of the coefficient circuits in the feedback and/or feed forward control system are reduced to eliminate the influences of the above-mentioned problems.

As shown in Fig. 1, an apparatus for controlling steering of wheels of a vehicle, or controlling variables representing vehicle behaviors comprises: a steering sensor I for detecting a steering angle of a steering wheel; vehicle behavior sensor II for detecting the variables representing vehicle behaviors; a control means III comprising a feed forward signal operating means III₁, a feedback signal operating means III₂, and a control signal operating means III₃, the feed forward signal operating means III₁ being provided with a steering angle signal circuit III₁₁ for outputting a steering angle signal output from the steering sensor without processing, a steering angle signal operating circuit III₁₃, a steering angular velocity signal operating circuit III₁₆, an adder III₁₇ for adding signals output from the steering angle signal circuit III₁₁, the steering angle signal operating circuit III₁₃, and the steering angular velocity signal operating circuit III₁₆, and the steering angle signal operating circuit III₁₃ being further provided with a first coefficient circuit III₁₂ for multiplying the steering angle signal with a coefficient G₁, and the steering angular velocity signal operating circuit III₁₆ being further provided with a differentiator III₁₄ for calculating the steering angular velocity signal from the steering angle signal and a second coefficient circuit III₁₅ for multiplying the steering angular velocity signal with a coefficient G₂, the feedback signal operating means III₂ being provided with a vehicle behavior state variable signal operating circuit III₂₂ having a third coefficient circuit III₂₁ for multiplying the

signals for variables representing the vehicle behaviors, which are output from the vehicle behavior sensor, with a coefficient G_3 and being adapted to generate a signal output from the vehicle behavior state variable signal operating circuit III₂₂ as a feedback control signal, the control signal operating means III₃ being provided with an adder/subtractor III₃₁ for performing an addition or a subtraction of signals output from the feed forward signal operating means III₁, and the feedback signal operating means III₂ to produce a steering control signal; a driving means IV for amplifying a power of the steering control signal as an output from the control means III, and an actuator means V for so controlling as to provide an optimal steering angle to front wheels or rear wheels on the basis of an amplified output from the driving means IV.

The above-mentioned apparatus for controlling steering of wheels of a vehicle has the following functions and effects. In the steering sensor I, the steering angle of the steering wheel is converted into an electrical signal corresponding to the steering angle. In the vehicle behavior sensor II, the variables representing the vehicle behaviors are converted into electrical signals and the like corresponding to the variables representing the vehicle behaviors. In order to optimize the vehicle behaviors responding to the steering angle, the electrical signals output from the steering sensor I and the vehicle behavior sensor II are processed in the control means III. In the control means III, vehicle controllability for steering is improved by generating a signal representing a control steering angle exceeding the measured steering angle. This signal is generated by the feed forward signal operating means III₁. The feed forward signal operating means III₁ comprises the steering angular velocity signal operating circuit III₁₆ provided with the differentiator III₁₄ and the second coefficient circuit III₁₅ to differentially increase or decrease the steering angle, the steering angle operating circuit III₁₃ provided with the first coefficient circuit III₁₂ to correct the magnitude (coefficient G_1) of the measured steering angle, and the steering angle signal circuit III₁₁ for supplying the steering angle to the control means without processing. When the variables representing the vehicle behaviors are rapidly changed, these changes are suppressed by the feedback signal operating means III₂. The feedback signal operating means III₂ comprises the vehicle behavior signal operating circuit III₂₂ provided with the third coefficient circuit III₂₁ for multiplying the coefficient G_3 for determining the feedback amount with the signal from the vehicle behavior sensor II for detecting the variables representing the vehicle behaviors. Therefore, stability of the vehicle can be improved.

A steering angle δ of the steering wheel is converted into a feed forward signal having a value of $\delta + G_1 \cdot \dot{\delta} + G_2 \cdot \ddot{\delta}$ by the feed forward signal operating means III₁. The feed forward signal and the signal generated by the feedback signal operating means are subjected to an addition or subtraction in the control signal operating means III₃, thereby generating the steering control signal.

The driving means IV amplifies the steering control signal into an actuator drive signal for driving the actuator. The actuator drive signal is used to drive the actuator in the actuator means V so as to apply an optimal steering angle to at least one of the front and rear wheels.

In the conventional technique, the feed forward signal is obtained by multiplying the differential value of the steering wheel angle with the coefficient G_2 . When the driver abruptly turns the steering wheel, the steering wheel angle δ and a differential value $\dot{\delta}$ of the steering wheel angle are output. The vehicle is rapidly turned to cause an unexpected behavior. The driver must turn the steering wheel in a complicated manner. For this reason, according to the present invention, the influence of the differential value $\dot{\delta}$ is canceled by a value of a coefficient multiple of the steering wheel angle δ , thereby assuring steering stability.

By using the apparatus for controlling steering of wheels of a vehicle, as described above, the value of the multiple of the steering wheel angle coefficient can be subtracted in addition to an addition of the differential value of the steering wheel angle so as to prevent abrupt turning of the vehicle when the driver abruptly turns the steering wheel. Abrupt behaviors of the vehicle can be suppressed. As a result, the mental load on the driver can be reduced, and safety driving can be assured. In addition, the apparatus can be quickly operated in only the initial period of abrupt turning.

As for vehicle turning with a large radius, the value of a coefficient multiple of the steering wheel angle can be added. Understeering of the vehicle can be reduced and safety can be assured under feed forward control without degrading the dynamic characteristics of the vehicle. Therefore, auxiliary steering of the vehicle which is substantially free from disturbance and highly responsive can be performed.

When the driver turns the steering wheel with a guess against an accidental disturbance after an external force acts on the vehicle, the value of the coefficient multiple of the steering wheel angle is subtracted to reduce the influence of the differential value, thereby assuring a safe behavior of the vehicle.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS:

50 First Mode

The first mode of the present invention is shown in the block diagram of Fig. 4. A control means III is connected to a vehicle state detection sensor IV and a first coefficient circuit III₁₂. The vehicle state detection sensor IV detects vehicle travel state variable with the vehicle travel such as a vehicle velocity, a vehicle load, a wheel load, a vehicle wheel velocity, a vehicle wheel angular velocity, a road surface shape (e.g., sprung relative displacement and velocity), and so on. The control means III comprises a gain changing means III₄ for changing a coefficient of the first coefficient circuit III₁₂ on the basis of the signals for vehicle travel states.

The function and effect of the first mode having the above characteristic feature will be described below.

A steering sensor I detects a steering angle of a steering wheel and generates an electrical signal corresponding to the steering angle. A vehicle behavior sensor II detects a change in variables representing a vehicle behavior and generates an electrical signal corresponding to the change. The vehicle detection sensor VI detects the vehicle travel state such as a vehicle velocity, a vehicle load, a wheel load, and a vehicle wheel velocity and generates electrical signals corresponding to these state variables.

A feed forward signal operating means III₁ comprises a steering angle signal circuit III₁₁ for outputting the steering angle without processing, a steering angle signal operating circuit III₁₃ provided with the first coefficient circuit III₁₂ for correcting a magnitude (i.e., a coefficient G_1) of a steering angle for the detected steering angle, and a steering angle velocity signal operating circuit III₁₈ provided with a differentiator III₁₄ for differentiating the steering angle and a second coefficient circuit III₁₅. In order to optimize the vehicle behaviors for the steering angle and the like detected as the electrical signals output from the steering sensor I and the vehicle behavior sensor II, the feed forward signal operating means III₁ in the control means III converts the input steering angle δ into a feed forward signal $\delta + G_1 \cdot \dot{\delta} + G_2 \cdot \delta$ and a steering angle exceeding the detected steering wheel angle is applied to shorten response time of the vehicle.

In a circuit III₂ for operating variables representing vehicle behaviors, having a third coefficient circuit III₂₁ for multiplying a signal from the vehicle behavior sensor II with a coefficient G_3 for determining a feedback value, the vehicle behavior state variable α is converted into a feedback signal $G_3 \cdot \alpha$. When the variables representing the vehicle behaviors are abruptly changed, the feedback signal is used to suppress the abrupt change, thereby stabilizing traveling of the vehicle.

A difference between the feed forward signal generated by the feed forward signal operating means and the feedback signal generated by the feedback signal operating means is calculated by an adder/subtractor III₃₁ in the control signal operating means III₃ to generate a steering control signal.

The steering control signal is amplified by the driving means IV as an actuator drive signal for driving the actuator. The actuator drive signal is used to drive the actuator in the actuator means V so as to apply an optimal steering angle of either the front or rear wheels or both.

The gain changing means III₄ can change the coefficient (to be referred to as a gain G) G_1 of the first coefficient circuit III₁₂ on the basis of the signals for vehicle travel state variable with the vehicle travel, such as a vehicle velocity, a vehicle load, a wheel load, and a vehicle wheel velocity, output from the vehicle state detection sensor VI.

With the above arrangement, the gain G_1 of the first coefficient circuit III₁₂ can be changed in accordance with the vehicle states such as a vehicle velocity, a vehicle load, a wheel load, and a vehicle wheel velocity. Even if the vehicle velocity is changed, the controllability for the behaviors for steering of the vehicle can be kept constant. Therefore, vehicle controllability and vehicle stability can be improved.

Second Mode

The second mode of the present invention is shown in the block diagram of Fig. 5.

A control means III is connected to a vehicle state detection sensor VI for detecting vehicle travel state variable with the vehicle travel, representing the vehicle, such as a vehicle velocity and a vehicle load and/or an outside environmental situation detection sensor VII for detecting an outside environmental situation such as a road surface condition and a first coefficient circuit III₁₂. The control means III comprises a gain changing means III₄ for changing a coefficient G_1 of the first coefficient circuit III₁₂ on the basis of signals for vehicle travel state variable with the vehicle travel and output from the vehicle state detection sensor VI and/or signals for state variables representing outside environmental situations and output from the outside environmental situation detection sensor VII.

The function and effect of the second mode having the above characteristic feature will be described below.

A steering sensor I converts a steering angle of a steering wheel into an electrical signal. A vehicle behavior sensor II converts a vehicle behavior state variable into an electrical signal. These electrical signals from the steering sensor I and the vehicle behavior sensor II are processed in the control means III so as to optimize the vehicle behaviors for the steering angle. More specifically, a feed forward signal operating means III₁ converts a steering wheel angle δ into a feed forward signal $\delta + G_1 \cdot \dot{\delta} + G_2 \cdot \delta$. The feed forward signal generating means comprises a steering angular velocity signal operating circuit III₁₈ provided with a differentiator III₁₄ for differentiating the steering angle and a second coefficient circuit III₁₅, a steering angle signal operating means III₁₃ provided with the first coefficient circuit III₁₂ for correcting a steering angle magnitude of the detected steering angle, and a steering angle signal circuit III₁₁ for transmitting the steering angle without processing to the control means.

In a circuit III₂₂ for operating signals for variables representing vehicle behaviors, having a third coefficient circuit III₂₁ for multiplying a signal from the vehicle behavior sensor II with a coefficient G_3 for determining a feedback value, the vehicle behavior state variable α is converted into a feedback signal $G_3 \cdot \alpha$.

A difference between the feed forward signal generated by the feed forward signal operating means and the feedback signal generated by the feedback signal operating means is calculated by an adder/subtractor III₃₁ in the control signal operating means III₃ to generate a steering control signal.

The steering control signal is amplified by the driving means IV as an actuator drive signal for driving the actuator. The actuator drive signal is used to drive the actuator in the actuator means V so as to apply an optimal steering angle of either the front or rear wheels or both.

The gain changing means III₄ can change the coefficient (gain) G_1 of the first coefficient circuit III₁₂ on the basis of the signals for vehicle travel state variables with the vehicle travel, such as a vehicle velocity, a vehicle load, a wheel load, and a vehicle wheel velocity and/or the signals for state variables representing outside environmental situations such as a road surface condition. When the gain changing means III₄ changes the gain G_1 on the basis of the vehicle velocity, the vehicle load, and the road surface condition, all of which are represented by the electrical signals corresponding thereto and output from the vehicle state detection sensor VI and the outside environmental situation detection sensor VII, the response characteristics of the vehicle behaviors for steering can be kept constant even if the vehicle velocity is changed, thereby further improving vehicle controllability and vehicle stability.

20 Third Mode

The third mode of the present invention is shown in the block diagram of Fig. 6. In the arrangement of the second mode, the gain changing means III₄ is connected to the first coefficient circuit III₁₂ and the second coefficient circuit III₁₅. The coefficients in the first and second coefficient circuits III₁₂ and III₁₅ are changed on the basis of the signals for vehicle travel state variables with the vehicle travel and output from the vehicle state detection sensor and/or the signals for state variables representing outside environmental situations and output from the outside environmental situation detection sensor.

The function and the effect of the third mode with the above characteristic feature will be described below.

The gain G_2 of the second coefficient circuit III₁₅ included in the feed forward signal operating means III₁ is increased when the gain G_1 of the first coefficient circuit III₁₂ is large. However, when the gain G_1 of the first coefficient circuit III₁₂ is small, the gain G_2 is decreased accordingly.

With the above arrangement, the following effect is obtained when the differential value of the steering angle is small as in the case wherein the driver easily changes the lanes in a wide road.

In addition to an increase in gain G_1 of the first coefficient circuit III₁₂ for correcting the magnitude of the steering angle signal, the gain G_2 of the second coefficient circuit III₁₅ for correcting the magnitude of the differential value of the steering angle is increased to reduce understeering so as not to cause degradation of the vehicle dynamic characteristics, i.e., excessive turning of the steering wheel, on the basis of the signals for the vehicle travel state variable with the vehicle travel and output from the vehicle state detection sensor VI and/or the signals for state variables representing outside environmental situations and output from the outside environmental situation detection sensor VII.

When the gains G_1 and G_2 of the first and second coefficient circuits III₁₂ and III₁₅ are kept small for the leading edges of the steep steering angle signal curve and the steep differential value curve of the steering angle signal, oversteering of the vehicle can be reduced and stable vehicle behaviors can be assured. A better control effect than that of the second mode can be obtained. Therefore, better vehicle controllability and vehicle stability can be guaranteed.

Fourth Mode

The fourth mode of the present invention is shown in the block diagram of Fig. 7. In the arrangement of the third mode, the gain changing means III₄ is connected to the first, second, and third coefficient circuits III₁₂, III₁₅, and III₂₁. The coefficients of the first, second, and third coefficient circuits III₁₂, III₁₅, and III₂₁ can be changed on the basis of the signals for vehicle travel state variables with the vehicle travel and output from the vehicle travel state detection sensor and/or the signals for state variables representing outside environmental situations and output from the outside environmental state detection sensor.

The function and the effect of the fourth mode having the above characteristic feature will be described below.

The gain G_3 of the third coefficient circuit III₂₁ included in the feedback signal operating means III₂ is

decreased when the gains G_1 and G_2 of the first and second coefficient circuits III_{12} and III_{15} included in the feed forward signal operating means III_1 are large, i.e., when the vehicle behavior response to the detected steering angle applied by the driver is high. However, when the gains G_1 and G_2 of the first and second coefficient circuits III_{12} and III_{15} in the feed forward signal operating means III_1 are small, i.e., when the vehicle behavior response to the steering angle applied by the driver is low, the gain G_3 of the third coefficient circuit III_{21} in the feedback signal operating means III_2 is increased. Therefore, a better control effect than the third mode of the present invention can be obtained.

Fifth Mode

The fourth mode of the present invention is shown in the block diagram of Fig. 8. In the arrangement of the fourth mode, the gain changing means III_4 is connected to the vehicle state detection sensor VI and/or the outside environmental situation detection sensor VII, and the steering sensor I and/or the steering angular velocity signal operating circuit III_{18} . The coefficients or gains (G_1 to G_3) of the first to third coefficient circuits can be changed on the basis of the signals for vehicle travel state variable with the vehicle travel and output from the vehicle state detection sensor VI and/or the signals for state variables representing the outside environmental situations and output from the outside environmental situation detection sensor VII, and the steering angle signal from the steering sensor I and/or the steering angular velocity signal from the steering angular velocity signal operating circuit III_{18} .

The function and effect of the fifth mode having the above characteristic feature will be described below.

The feed forward signal operating means III_1 in the control means III calculates the control signal on the basis of the steering angle of the steering wheel. The control signal calculated on the basis of the variables representing the vehicle behaviors is calculated by the feedback signal operating means III_2 . These control signals are processed by the control signal operating means III_3 , thereby generating an optimal steering angle.

The optimal gains of the first and second coefficient circuits II_{12} and II_{15} in the feed forward signal operating means III_1 and the third coefficient circuit III_{21} in the feedback signal operating means III_2 are set by the gain changing means III_4 in the control means III.

These gains are preferably not only changed by the vehicle travel state variable with the vehicle travel such as a vehicle velocity and a vehicle load and the state variables representing the outside environmental situations such as a road surface state, but also changed by the will of the driver. More preferably, the gains are automatically changed.

The present inventors proposed the gain changing means III_4 for resetting the gains on the basis of the steering wheel angle and the steering velocity, both of which serve as factors for reflecting the driver's will.

The gain changing means III_4 sets small gains G_1 and G_2 and a large gain G_3 when the steering wheel angle is small. In this case, the gain changing means III_4 determines that the driver does not intend to turn the steering wheel. However, when the steering wheel angle is increased, the gain changing means III_4 sets large gains G_1 and G_2 and a small G_3 . In this case, the gain changing means III_4 determines that the driver intends to turn the steering wheel. When the steering velocity is high, the gain changing means III_4 determines that the driver wants to abruptly turn the steering wheel. In this case, the gains G_1 , G_2 , and G_3 are set in the same manner as in the above case wherein the steering wheel angle is large.

When the control means III comprises the above gain changing means III_4 , the magnitude of the feed forward signal output from the feed forward signal operating means III_1 is kept small at a small steering wheel angle. In this case, the magnitude of the feedback signal output from the feedback signal operating means III_2 is increased. Therefore, vehicle stability can be further improved since the steering control signal includes the feedback signal as a major component. However, when the steering wheel angle is large and a steering wheel angular velocity is high, the magnitude of the feed forward signal output from the feed forward signal operating means III_1 is increased while the feedback signal output from the feedback signal operating means III_2 is decreased. The steering control signal has the feed forward signal as a major component, and therefore the response time of the vehicle can be further shortened.

In other words, vehicle stability and vehicle controllability can be improved by the steering wheel angle and the steering velocity, and a better control effect can be obtained.

Sixth Mode

The sixth mode of the present invention is shown in the block diagram of Fig. 9. In the fourth mode, a gain changing means III_4 is connected to a vehicle state detection sensor VI and/or an outside environmental situation detection sensor VII, a steering sensor I and/or a steering angular velocity signal operating circuit

III₁₆, and a vehicle behavior sensor II. Gains (G_1 to G_3) of first to third coefficient circuits can be changed on the basis of the signals for vehicle travel state variable with the vehicle travel and output from the vehicle state detection sensor VI and/or the signals for state variables representing the outside environmental situations and output from the outside environmental situation detection sensor VII, the steering angle signal from the steering sensor I and/or the steering angular velocity signal from the steering angular velocity signal operating circuit III₁₆, and the signals for variables representing vehicle behaviors and output from the vehicle behavior sensor II.

The function and effect of the sixth mode having the above characteristic feature will be described below.

The control signal based on the vehicle travel state variable with the vehicle travel is calculated by the feed forward signal operating means III₁ in the control means III. The control signal based on the variables representing vehicle behaviors is calculated by the feedback signal operating means III₂. These control signals are processed by the control signal operating means III₃, thereby generating an optimal steering control signal.

The optimal gains G_1 and G_2 of the first and second coefficient circuits III₁₂ and III₁₅ in the feed forward signal operating means III₁ and the optimal gain G_3 of the third coefficient circuit III₂₁ in the feedback signal operating means III₂ are set by the gain changing means III₄ in the control means III.

When the gains are determined by the steering angular velocity or the vehicle velocity sensor VI, the following problem occurs. For example, when the steering sensor I for detecting the steering angle or the vehicle velocity sensor VI for detecting the steering angular velocity is failed, the control means III does not have a fail-safe function for such a failure. The resultant steering control angle is different from an accurate control angle, which may endanger the driver.

The vehicle behaviors which cannot be measured (or estimated) by only the steering angle signal output from the steering sensor I and the steering angular velocity signal are input as information for changing the gains set by the gain changing means III₄. More accurate control can be therefore achieved.

By inputting the vehicle travel state variable with the vehicle travel and the vehicle behaviors to the gain changing means III₄, the control effect can be greatly improved by a relatively simple mechanism for performing complicated control.

30 Seventh Mode

The seventh mode of the present invention is shown in the block diagram of Fig. 10. In the arrangement of the second mode, the gain changing means III₄ is connected to : at least one of the vehicle state detection sensor VI for detecting the signals for vehicle travel state variable with the vehicle travel such as a vehicle velocity and a vehicle load and/or the outside environmental situation detection sensor VII for detecting the signals for state variables representing the outside environmental situations such as a road surface state, rainfall, and an ambient temperature, and/or the steering sensor I and/or the steering angular velocity signal operating circuit III₁₆ and/or the vehicle behavior sensor II ; and the first coefficient circuit III₁₂, the second coefficient circuit III₁₅ and/or the third coefficient circuit III₂₁. The gain changing means comprises : a sense-of-situation determining means III₄₁ for determining a present situation judged by the human senses on the basis of a signal of at least one of the vehicle state detection sensor VI and/or the outside environmental situation detection sensor VII and/or the steering sensor I and/or the steering angular velocity signal operating circuit III₁₆ and/or the vehicle behavior sensor II ; a vehicle state determining means III₄₂ for determining the required degree of vehicle stability and vehicle controllability on the basis of the determination result from the sense-of-situation determining means III₄₁; and a gain deciding means III₄₃ for deciding the gains G_1 to G_3 on the basis of the determination result from the vehicle state determining means III₄₂ and outputting the optimal gains to the first coefficient circuit III₁₂ and/or the second coefficient circuit III₁₅ and/or the third coefficient circuit III₂₁.

The function and the effect of the seventh mode having the above characteristic feature will be described below.

The gain changing means III₄ receives at least one of the signals for vehicle travel state variable with the vehicle travel such as the vehicle velocity and the vehicle load and output from the vehicle state detection sensor IV, the signals for state variables representing outside environmental situations such as a road surface state, rainfall, and an ambient temperature and output from the outside environmental situation detection sensor VII, the steering angle signal from the steering sensor I, the steering angular velocity signal from the steering angular velocity signal operating circuit III₁₆, and the signals for variables representing vehicle behaviors and output from the vehicle behavior sensor II.

The sense-of-situation determining means III₄₁ determines the current situation, i.e., the degree of the

vehicle velocity, the degree of the vehicle load, and the degree of the steering angle, on the basis of the input signal.

A necessary measure M for the vehicle response in units of behavior variables with slight ambiguity given by the situations determined by the vehicle state determining means III₄₂ is calculated in accordance with conditions (1) to (8) given as follows :

- (1) If the vehicle velocity is high, the response time is prolonged.
- (2) If the vehicle load is heavy, the response time is prolonged.
- (3) If the road is slippery, the response time is prolonged.
- (4) If the rainfall is high, the response time is prolonged.
- (5) If the ambient temperature is low, the controllability is prolonged.
- (6) If the steering angle is large, the controllability is shortened.
- (7) If the steering angular velocity is high, controllability is shortened.
- (8) If the variables representing vehicle behaviors are large, the response time is prolonged.

If the detected situation is given according to condition (1), an expression is given such that "if the vehicle velocity is relatively high (i.e., a value corresponding to the situation determined by the sense-of-situation determining means III₄₁), the controllability is prolonged accordingly". For example, as shown in Fig. 10, the measure for the degree of vehicle velocity felt by the human senses is determined by the sense-of-situation determining means III₄₁ when the actual vehicle velocity is detected by the sensor. The value of the degree obtained by the sense-of-situation determining means III₄₁ is converted into the necessary measure M (the necessary measure for response in this case) by the vehicle state determining means III₄₂ provided with a function operation section III₄₂₁.

Gains G₁ to G₃ suitable for the current situation are decided by the gain deciding means III₄₃ on the basis of the necessary measure M. The corresponding gain is supplied to at least one of the first to third coefficient circuits III₁₂, III₁₅, and III₂₁.

By arranging such a gain changing means III₄, an accurate control value can be given for any situation which can be hardly expressed (i.e., the degree of the vehicle velocity or the degree of steering angle can be accurately expressed). Therefore, all situations can be controlled, and a better control effect can be obtained.

Eighth Mode

The eighth mode of the present invention is shown in the block diagram of Fig. 11. In the seventh mode, the gain deciding means III₄₃ included in the gain changing means III₄ includes a memory III₄₄ for calculating the gains on the basis of the necessary measure for vehicle stability and vehicle response and storing the calculated values, and a gain selector III₄₅ for selecting the gain values from the memory III₄₄ on the basis of the determination value from the vehicle state determining means III₄₂.

The function and effect of the eighth mode having the above characteristic feature will be described below.

The gain deciding means III₄₃ receives the necessary measure for vehicle stability and response output from the vehicle state determining means III₄₂. The memory III₄₄ in the gain deciding means III₄₃ prestores gains G_{1n} to G_{3n} (where n is the number of gains corresponding to the necessary measures) corresponding to the calculated necessary measures. The gains G_{1n} to G_{3n} are gain values for achieving optimal dynamic characteristics of the vehicle on the basis of the necessary measures for vehicle stability and response.

The gain selector III₄₅ selects the gain values suitable for the current situation on the basis of the input necessary measures. The selected gains are output to the first to third coefficient circuits III₁₂, III₁₅, and III₂₁.

By providing the gain deciding means III₄₃ described above, the gain changing means III₄ can be obtained wherein the gain values corresponding to the necessary measures for vehicle stability and response can be immediately supplied to the first to third coefficient circuits III₁₂, III₁₅, and III₂₁. As a result, flexible control corresponding to given situations can be achieved.

Ninth Mode

The ninth mode of the present invention is shown in the block diagram of Fig. 12. The gain deciding means III₄₃ included in the gain changing means III₄ includes a memory III₄₄ for storing a stability priority gain for maximizing vehicle stability and a response priority gain for maximizing the vehicle response, and a gain calculation section III₄₆ for weighting these two gains on the basis of the determination value from a vehicle state determining means III₄₂ and calculating gains suitable for the current situation.

The function and effect of the ninth mode having the above characteristic feature will be described

below.

The gain deciding means III₄₃ receives the necessary measures for vehicle stability and response output from the vehicle state determining means III₄₂. Precalculated stability priority gains G₁₀ to G₃₀ for maximizing vehicle stability and precalculated response priority gains G₁₁ to G₃₁ for maximizing the vehicle response are stored in the memory III₄₄. These priority gains are the basic gains for determining their values.

The gain operation section III₄₈ multiplies the stability priority gains G₁₀ to G₃₀ with weighting coefficients corresponding to the necessary stability measure representing the degree of stability improvement and the response priority gains G₁₁ to G₃₁ with weighting coefficients corresponding to the necessary response measure. The products are added to calculate gains G₁ to G₃, and the gains G₁ to G₃ are respectively output to the first to third coefficient circuits III₁₂, III₁₅, and III₂₁.

When the gain deciding means III₄₃ having the arrangement described above is included in the gain changing means III₄, the gain changing means III₄ can easily supply the gain values corresponding to the necessary stability and response measures to the first to third coefficient circuits III₁₂, III₁₅, and III₂₁. Therefore, flexible control corresponding to given situations can be achieved. A large volume of data need not be stored in the memory III₄₄, and the size of the gain changing means III₄ can be reduced. Therefore, the overall system arrangement can be compact and inexpensive, thus improving efficiency.

Tenth Mode

The tenth mode of the present invention is shown in the block diagram of Fig. 13. A gain changing means III₄ comprises: a vehicle behavior state variable estimating means III₄₁ for estimating the variables representing vehicle behaviors on the basis of a steering angle signal output from the steering sensor I and signals for vehicle travel state variable with the vehicle travel and output from the vehicle state sensor VI; a μ estimating means III₄₂ for estimating friction (μ) between the road surface and the wheel surfaces on the basis of the vehicle behavior state variable estimation signal output from the vehicle behavior state variable estimating means III₄₁ and the signals for variables representing vehicle behaviors and output from the vehicle behavior sensor II; and a coefficient circuit coefficient changing means III₄₃ for changing the coefficient of at least one of first, second, and third coefficient circuits III₁₂, III₁₅, and III₂₁ on the basis of the μ estimation signal output from the μ estimating means III₄₂. Therefore, the gain changing means III₄ supplies an optimal coefficient to a corresponding coefficient circuit.

The function and effect of the tenth mode having the above characteristic feature will be described below.

The vehicle behavior state variable estimating means III₄₁ in the gain changing means III₄ estimates the variables representing vehicle behaviors on the basis of the steering control signal output from the control signal operating means III₃ and the signals for vehicle travel state variables with the vehicle travel and output from the vehicle state detecting sensor VI. The μ estimating means III₄₂ estimates friction (μ) between the road surface and the wheel surfaces on the basis of the vehicle behavior state variable estimation signal output from the vehicle behavior state variable estimating means III₄₁ and the signals for variables representing vehicle behaviors such as a yaw rate and a lateral acceleration output from the vehicle behavior sensor II. The coefficient circuit coefficient changing means III₄₃ changes the coefficient of at least one of the first, second, and third coefficient circuits III₁₂, III₁₅, and III₂₁ on the basis of the μ estimation signal output from the μ estimating means III₄₂. Therefore, an optimal coefficient corresponding to the current situations of the wheels and/or the road surface is supplied to the corresponding coefficient circuit.

As described above, the coefficients (G₁, G₂, and G₃) are automatically changed on the basis of the μ estimation value so as to optimally satisfy the current situations of the wheels and/or the road surface. Zig-zag driving or a spin which is caused by oversteering by the driver can be prevented. In addition, even if the driver does not notice a change in μ , safety driving can be assured. Therefore, excellent driving stability can be achieved.

Eleventh Mode

The eleventh mode of the present invention is shown in the block diagram of Fig. 14. A vehicle behavior state variable estimating means III₄₁ estimates the variables representing vehicle behaviors on the basis of the steering control signal output from the control signal operating means III₃ and the signals for vehicle travel state variable with the vehicle travel and output from the vehicle state detection sensor VI. The μ estimating means III₄₂ comprises comparing means III₄₂₁ for comparing the peak value of the vehicle behavior state variable estimation signal output from the vehicle behavior state variable estimating means III₄₁ with the peak value of the vehicle behavior state variable signal output from the vehicle behavior sensor

II, and a μ determining means III₄₂₂ for estimating friction μ on the basis of a comparison result output from the comparing means III₄₂₁.

The above peak value comparison is performed by comparing magnitudes of the peak values of the vehicle behavior state variable estimation signal and the behavior state variable signal and/or a phase difference between their peaks.

The function and effect of the eleventh mode having the above characteristic feature will be described below.

The vehicle behavior state variable estimating means III₄₁ estimates the variables representing vehicle behaviors on the basis of a vehicle model obtained by mathematically modeling the vehicle behaviors on the smooth road by using the steering control signal output from the control signal operating means III₃, the signals for vehicle travel state variables with the vehicle travel and output from the vehicle state sensor VI, and the steering control signal output from the control signal operating circuit III₃₁.

The comparing means III₄₂₁ in the μ estimating means III₄₂ estimates the vehicle behavior state variable estimation signal output from the vehicle behavior variable estimating means III₄₁, e.g., the yaw rate and/or the lateral acceleration generated on the smooth road for the signals representing the current steering angle, the current vehicle travel state variables with the vehicle travels, and the steering control signal, calculates peaks of the signals, calculates a peak value of the signal for variable representing the vehicle behavior such as the yaw rate or the lateral acceleration output from the vehicle behavior sensor II, and compares the calculated peak values. This comparison operation is performed by comparing the magnitude of the peak values and/or the phase difference between their peaks.

The μ determining means III₄₂₂ estimates friction μ on the basis of the comparison result output from the comparing means III₄₂₁.

Unlike the conventional technique wherein the friction μ is estimated by the slip ratio of the wheels at the time of stop or start of the vehicle, the friction μ is estimated by the variables representing the vehicle behaviors according to the present invention. Therefore, the friction μ for determining the cornering forces of the wheels in the normal dynamic characteristics can be estimated.

The road surface change caused by a change in environmental situation during vehicle traveling can be estimated by the variables representing the vehicle behaviors. The coefficients can be set in the coefficient circuits by using the estimated values. Therefore, an excellent adaptive steering control system can be arranged, and stable steering with safety can be provided.

Twelfth Mode

The twelfth mode of the present invention is shown in the block diagram of Fig. 15. A gain changing means III₄ comprises: the vehicle behavior state variable estimating means III₄₁ for estimating the variables representing the vehicle behaviors on the basis of the steering control signal output from the control signal operating means III₃ and the signals for vehicle travel state variable with the vehicle travel and output from the vehicle state detection sensor VI; a μ estimating means III₄₂ for estimating friction μ between the wheels and the road surface on the basis of the vehicle behavior state variable estimation signal output from the vehicle behavior state variable estimating means III₄₁ and the vehicle behavior state variable signal output from the vehicle behavior sensor II; slip ratio calculating means III₄₄ for calculating a slip ratio of each vehicle wheel on the basis of the signals for vehicle travel state variable with the vehicle travel and output from the vehicle state detection sensor VI; and a coefficient circuit coefficient changing means III₄₃ for changing a coefficient of at least one of first, second, and third coefficient circuits III₁₂, III₁₅, and III₂₁ on the basis of the μ estimation signal output from the μ estimating means III₄₂ and the slip ratio signal output from the slip ratio calculating means III₄₄.

The function and the effect of the twelfth mode having the above characteristic feature will be described below.

The vehicle behavior state variable estimating means III₄₁ in the gain changing means III₄ estimates the variables representing the vehicle behaviors on the basis of the steering control signal output from the control signal operating means III₃ and the signals for vehicle travel state variables with the vehicle travel and output from the vehicle state detection sensor VI. The μ estimating means III₄₂ estimates friction μ between each wheel and the road surface on the basis of the vehicle behavior state variable estimation signal output from the vehicle behavior state variable estimating means III₄₁ and the behavior state variable signal output from the vehicle behavior sensor II. The slip ratio calculating means III₄₄ calculates a slip ratio of each wheel on the basis of the signals for vehicle travel state variables with the vehicle travel and output from the vehicle state detection sensor VI, the vehicle velocity, and the vehicle wheel velocity. The coefficient circuit coefficient changing means III₄₃ changes a coefficient of at least one of the first, second, and third

coefficient circuits III₁₂, III₁₅, and III₂₁ on the basis of the μ estimation signal output from the μ estimating means III₄₂ and the slip ratio signal output from the slip ratio calculating means III₄₄.

With the above arrangement, the slip ratio is used as a reference for changing the gain. For example, when the gains must be changed to improve stability of the vehicle so as to prevent zig-zag traveling or a spin of the vehicle at the time of start or stop of the vehicle on a road having a low friction value μ or during abrupt acceleration or deceleration, the gains can be changed prior to changes in variables representing the vehicle behaviors.

In addition to steering control corresponding to road surface condition changes caused by changes in outside environmental situations during vehicle traveling, steering control corresponding to vehicle wheel condition changes caused by changes in driving force during an acceleration or deceleration operation upon depression or release of an accelerator pedal can also be performed to improve safety of the vehicle. Therefore, vehicle handling can be further improved.

Thirteenth Mode

The thirteenth mode of the present invention is shown in the block diagram of Fig. 16. A gain changing means III₄ comprises: a vehicle behavior state variable estimating means III₄₁ for estimating the variables representing the vehicle behaviors on the basis of the steering control signal output from the control signal operating means III₃ and the signals for vehicle travel state variables with the vehicle travel and output from the vehicle state detection sensor VI; a μ estimating means III₄₂ for estimating friction μ on the basis of the vehicle behavior state variable estimation signal output from the vehicle behavior state variable estimating means III₄₁ and the vehicle behavior state variable signal output from the vehicle behavior sensor II; a road surface shape estimating means III₄₅ for estimating a shape of a road surface on the basis of the signals for vehicle travel state variable with the vehicle travel and output from the vehicle state detection sensor VI; and a coefficient circuit coefficient changing means III₄₃ for changing a coefficient of at least one of first, second, and third coefficient circuits III₁₂, III₁₅, and III₂₁ on the basis of the μ estimation signal output from the μ estimating means III₄₂ and the estimated road surface shape signal output from the road surface shape estimating means III₄₅.

The function and effect of the thirteenth mode having the above characteristic feature will be described below.

The vehicle behavior state variable estimating means III₄₁ in the gain changing means III₄ estimates the vehicle travel state variables with the vehicle travel behaviors on the basis of the steering control signal output from the control signal operating means III₃ and the signals for vehicle travel state variable with the vehicle travel and output from the vehicle state detection sensor VI. The μ estimating means III₄₂ estimates friction μ on the basis of the vehicle behavior state variable estimation signal output from the vehicle behavior state variable estimating means III₄₁ and the signals for variables representing the vehicle behaviors and output from the vehicle behavior sensor II. Subsequently, the road surface shape estimating means III₄₅ estimates the shape of the road surface which contacts all vehicle wheels on the basis of the vehicle velocity output from the vehicle state detection sensor VI and the signals for state variables representing a suspension displacement of each vehicle wheel and a vehicle velocity. The coefficient circuit coefficient changing means III₄₃ changes a coefficient of at least one of the first, second, and third coefficient circuits III₁₂, III₁₅, and III₂₁ on the basis of the μ estimation signal output from the μ estimating means III₄₂ and the estimated road surface shape signal output from the road surface shape estimating means III₄₅.

In a conventional apparatus, vibrations caused by bumps on the road are transmitted to the vehicle body and hence the vehicle behavior sensor. The influenced signal for state variable representing a vehicle behavior is used as a steering control signal, thus causing an operation error.

According to the thirteenth mode of the present invention, the estimated road surface shape signal is used as a reference for the gain changing means. Therefore, stability and reliability of the steering control system for the road surface shape can be further improved.

In addition to the vehicle wheel slip state variable changed by changes in outside environmental situations or operations of an accelerator pedal during vehicle traveling, optimal steering control can be provided so as to compensate for the changes in traveling road surface condition. Vehicle safety can be further improved, and vehicle handling can also be improved.

Fourteenth Mode

The fourteenth mode of the present invention is shown in the block diagram of Fig. 17. A gain changing means III₄ comprises: a vehicle behavior state variable estimating means III₄₁ for estimating the vehicle

travel state variables with the vehicle travel behaviors on the basis of the steering control signal output from the control signal operating means III₃ and the signals for vehicle travel state variable with the vehicle travel and output from the vehicle state detection sensor VI ; a μ estimating means III₄₂ for estimating friction μ between the vehicle wheels and the road surface on the basis of the vehicle behavior state variable estimation signal output from the vehicle behavior state variable estimating means III₄₁ and the signals for variables representing the vehicle behaviors and output from the vehicle behavior sensor II ; a sensor abnormality detecting means III₄₆ for detecting abnormalities of the steering sensor I, the vehicle behavior sensor II, and the vehicle state detection sensor VI ; and a coefficient circuit coefficient changing means III₄₃ for changing a coefficient of at least one of first, second, and third coefficient circuits III₁₂, III₁₆, and III₂₁ on the basis of the μ estimation signal output from the μ estimating means III₄₂ and the sensor abnormality detection signal output from the sensor abnormality detecting means III₄₆.

The function and effect of the fourteenth mode having the above characteristic feature will be described below.

The vehicle behavior state variable estimating means III₄₁ in the gain changing means III₄ estimates the vehicle travel state variables with the vehicle travel behaviors on the basis of the steering control signal output from the control signal operating means III₃ and the signals for vehicle travel state variable with the vehicle travel and output from the vehicle detection sensor VI. The μ estimating means III₄₂ estimates friction μ between the vehicle wheels and the road surface on the basis of the vehicle behavior state variable estimation signal output from the vehicle behavior state variable estimating means III₄₁ and the vehicle behavior state variable signal output from the vehicle behavior sensor II. The sensor abnormality detecting means III₄₆ detects abnormalities of the sensors when output values of the steering sensor I, the vehicle behavior sensor II, and the vehicle state detection sensor VI fall outside the allowable range of the preset values in view of the vehicle behavior or when the sensor outputs are compared with each other and comparison results indicate an abnormality. The coefficient circuit coefficient changing means III₄₃ changes a coefficient of at least one of the first, second, and third coefficient circuits III₁₂, III₁₆, and III₂₁ on the basis of the μ estimation signal output from the μ estimating means III₄₂ and the sensor abnormality detection signal output from the sensor abnormality detecting means III₄₆.

With the above arrangement, the operation errors of the steering control system which are caused by sensor failures can be prevented to further improve safety and reliability.

When optimal steering control corresponding to changes in outside environmental situations and changes in vehicle travel state variable with the vehicle travel by driver's operations is required, the vehicle can be constantly kept safe even if the sensors are accidentally malfunctioned or failed, thereby improving vehicle handling.

(Description of Principle of μ Estimation)

A method of estimating friction μ between the vehicle wheels and the road surface in an apparatus for controlling steering of wheels of a vehicle according to the present invention will be briefly exemplified.

Equations of motion for translating lateral motion y and yaw motion ψ as follows :

$$m \cdot \ddot{y} = 2 (F_f + F_r) \quad \dots (1)$$

$$I_z \cdot \ddot{\psi} = 2 (a_f \cdot F_f - a_r \cdot F_r) \quad \dots (2)$$

$$F_f = -\mu \cdot m_f \{ (\dot{y} - u_0 \cdot \psi + a_f \cdot \dot{\psi}) / u_0 \} - \delta_f - u_f \quad \dots (3)$$

$$F_r = -\mu \cdot m_r \{ (\dot{y} - u_0 \cdot \psi - a_r \cdot \dot{\psi}) / u_0 \} - u_r \quad \dots (4)$$

where

m : the vehicle weight

m_f : the front load of the vehicle

m_r : the rear load of the vehicle

μ : the friction

u_f : the auxiliary steering angle for the front wheels

u_r : the auxiliary steering angle for the rear wheels

5 I_z : the yaw inertia moment of the vehicle

a_f : the distance between the front axle of the vehicle and its center of gravity

a_r : the distance between the rear axle of the vehicle and its center of gravity

c_f : the cornering power of the front wheels of the vehicle

c_r : the cornering power of the rear wheels of the vehicle

10 F_f : the cornering force of the front wheels of the vehicle

F_r : the cornering force of the rear wheels of the vehicle

u_0 : the vehicle velocity

ψ : the yaw angle of the vehicle

$\dot{\psi}$: the yaw rate of the vehicle

15 $\ddot{\psi}$: the yaw angular acceleration of the vehicle

y : the lateral displacement of the vehicle

\dot{y} : the lateral velocity of the vehicle

\ddot{y} : the lateral acceleration of the vehicle

δ_f : the front wheel steering angle of the vehicle

20 Equations (1) to (4) are synthesized as follows :

$$\dot{x}(t) = Ax(t) + [b_f(\delta_f(t) + u_f(t)) + b_r u_r(t)] \quad (5)$$

wherein $x(t)$, A , b_f , and b_r are defined as follows :

25

30

$$x(t) = \begin{bmatrix} y(t) \\ \dot{y}(t) \\ \psi(t) \\ \dot{\psi}(t) \end{bmatrix}$$

35

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & a_{22} & a_{23} & a_{24} \\ 0 & 0 & 0 & 1 \\ 0 & a_{42} & a_{43} & a_{44} \end{bmatrix}$$

40

... (6)

45

$$b_f = \begin{bmatrix} 0 \\ b_{f1} \\ 0 \\ b_{f2} \end{bmatrix}$$

50

$$b_r = \begin{bmatrix} 0 \\ b_{r1} \\ 0 \\ b_{r2} \end{bmatrix}$$

55

Elements in equations (6) are defined as follows :

$$\begin{aligned}
 a_{22} &= -2\mu(m_f + m_r) / (u_0 \cdot m) \\
 a_{23} &= 2\mu(m_f + m_r) / m \\
 a_{24} &= 2\mu(a_r \cdot m_r - a_f \cdot m_f) / (u_0 \cdot m) \\
 a_{42} &= 2\mu(a_r \cdot m_r - a_f \cdot m_f) / (u_0 \cdot m) \\
 a_{43} &= 2\mu(a_f \cdot m_f - a_r \cdot m_r) / I_z \\
 a_{44} &= -2\mu(a_f^2 \cdot m_f + a_r^2 \cdot m_r) / (u_0 \cdot I_z) \\
 b_{f1} &= 2\mu \cdot m_f / m \\
 b_{f2} &= 2\mu \cdot a_f \cdot m_f / m \\
 b_{r1} &= 2\mu \cdot m_r / I_z \\
 b_{r2} &= -2\mu \cdot a_r \cdot m_r / I_z
 \end{aligned} \quad \dots (7)$$

The yaw rate $\dot{\psi}$ and the lateral velocity \dot{y} are expressed below in accordance with equations (5) and (6). In the following equations, S represents a Laplacian operator.

$$\begin{aligned}
 g_1(S) \cdot \dot{\psi}(S) &= (d_1 \cdot S + d_0) \\
 &\quad (\delta_f(S) + u_f(S)) \\
 &\quad + (c_1 \cdot S + c_0) u_r(S) \\
 \text{for} \\
 g_1(S) &= S^2 - (a_{22} + a_{44})S \\
 &\quad + (a_{22} \cdot a_{44} - a_{24} \cdot a_{42} - a_{43}) \\
 d_1 &= b_{f2} \\
 d_0 &= b_{f1} \cdot a_{42} - b_{f2} \cdot a_{22} \\
 c_1 &= b_{r2} \\
 c_0 &= b_{r1} \cdot a_{42} - b_{r2} \cdot a_{22}
 \end{aligned} \quad \dots (8)$$

$$\begin{aligned}
 &g_2(s) \dot{y}(s) = (h_2 \cdot s^2 + h_1 \cdot s + h_0) \\
 &\quad (\delta_f(s) + u_f(s)) \\
 &\quad + (k_2 \cdot s^2 + k_1 \cdot s \\
 &\quad + k_0) u_r(s) \\
 &\text{for} \\
 &g_2(s) = s \cdot g_1(s) \\
 &h_2 = b_{f1} \\
 &h_1 = b_{f2} \cdot a_{24} - b_{f1} \cdot a_{44} \\
 &h_0 = b_{f2} \cdot a_{23} - b_{f1} \cdot a_{43} \\
 &k_2 = b_{r1} \\
 &k_1 = b_{r2} \cdot a_{24} - b_{r1} \cdot a_{44} \\
 &k_0 = b_{r2} \cdot a_{23} - b_{r1} \cdot a_{43}
 \end{aligned}
 \quad \dots (9)$$

From equation (9), the lateral acceleration \ddot{y} can be derived as follows :

$$\begin{aligned}
 g_1(s) \ddot{y}(s) &= (h_2 \cdot s^2 + h_1 \cdot s + h_0) \\
 &\quad (\delta_f(s) + u_f(s)) \\
 &\quad + (k_2 \cdot s^2 + k_1 \cdot s + k_0) u_r(s)
 \end{aligned}
 \quad \dots (10)$$

The coefficients of equations (8) and (10) are calculated using the specifications of the vehicle, the vehicle velocity u_0 , and the front and rear wheel loads m_f and m_r from the vehicle state detection sensor. The calculated coefficients, the driver's steering angle δ_r and the front and rear wheel steering angles u_f and u_r are used to solve equations (8) and (10), thereby estimating an estimated yaw rate $\dot{\psi}_m$ and an estimated lateral acceleration \ddot{y}_m . In this case, friction μ is given as a value for a smooth road (e.g., 0.8 to 1.0).

By using the estimated value $\dot{\psi}_m$ of the yaw rate and the estimated value \ddot{y}_m of the lateral acceleration are used to estimate the friction μ between the vehicle wheels and the road surface in the following manner with reference to Fig. 18.

The controllability of the yaw rate and the lateral acceleration is changed according to different friction values μ even if identical steering operations are performed. For example, if the friction value μ is small, the yaw rate and the lateral acceleration are decreased as compared with the case wherein the friction value μ is large. In addition, the leading edge of the characteristic curves of the yaw rate and the lateral acceleration are moderate. By using this nature, the friction value μ is estimated. Peak values of the estimated values $\dot{\psi}_m$ and \ddot{y}_m of the ideal yaw rate and the ideal lateral acceleration which are obtained on the smooth road (or an equivalent) and peak values of the detected yaw rate $\dot{\psi}$ and the lateral acceleration \ddot{y} are calculated. The magnitudes of the peak values and/or the phase difference between these peaks is compared to estimate the friction.

In the above estimation method, the friction μ is actually estimated by the front wheel steering system ($u_r = 0$) as follows :

(i) Ratios of magnitudes of the peak values of the frequencies of the friction values μ , the vehicle velocities, the vehicle travel state variables with the vehicle travel, and steering control signals, and/or phase differences between the peak values are stored as a map. Data associated with these peak values are

compared with each other, and the comparison results are subtracted from the data in the map, thereby estimating the friction μ .

(ii) The steady values of the $\dot{\psi}$ and the \dot{y} are represented as follows :

$$\begin{aligned}\dot{\psi} &= \{d_0(\delta_f + u_f) + C_0 \cdot u_r\} / (a_{22} \cdot a_{44} - a_{24} \cdot a_{42} - a_{43}) \\ &= s_1 / (s_2 - s_3/\mu) \quad (11)\end{aligned}$$

$$\begin{aligned}\dot{y} &= \{h_0(\delta_f + u_f) + k_0 \cdot u_r\} / (a_{22} \cdot a_{44} - a_{24} \cdot a_{42} - a_{43}) \\ &= s_4 / (s_2 - s_3/\mu) \quad (12)\end{aligned}$$

$$\left. \begin{aligned}s_1 &= \bar{d}_0 (\delta_f + u_f) + \bar{C}_0 \cdot u_r \\ s_2 &= \bar{a}_{22} \cdot \bar{a}_{44} - \bar{a}_{24} \cdot \bar{a}_{42} \\ s_3 &= \bar{a}_{43} \\ s_4 &= \bar{h}_0 (\delta_f + u_f) + \bar{k}_0 \cdot u_r \\ \bar{d}_0 &= \mu^2 (\bar{b}_{f1} \cdot \bar{a}_{42} - \bar{b}_{f2} \cdot \bar{a}_{22}) \\ \bar{C}_0 &= \mu^2 (\bar{b}_{r1} \cdot \bar{a}_{42} - \bar{b}_{r2} \cdot \bar{a}_{22}) \\ \bar{h}_0 &= \mu^2 (\bar{b}_{f2} \cdot \bar{a}_{23} - \bar{b}_{f1} \cdot \bar{a}_{43}) \\ \bar{k}_0 &= \mu^2 (\bar{b}_{r2} \cdot \bar{a}_{23} - \bar{b}_{r1} \cdot \bar{a}_{43}) \\ a_{ij} &= \mu \bar{a}_{ij} \quad (i, j = 1, 2, \dots, 4) \\ b_{ij} &= \mu \bar{b}_{ij} \quad (i = f, r \text{ and} \\ &\quad j = 1, 2, \dots, 4)\end{aligned} \right\} \dots (13)$$

The steady values of the estimated values are given in the same manner as in equations (11) and (12) as follows :

$$\dot{\psi}_m = s_1 / (s_2 - s_3/\mu_m) \quad (14)$$

$$\dot{y}_m = s_4 / (s_2 - s_3/\mu_m) \quad (15)$$

where μ_m is the friction value μ between the vehicle wheels and the road surface on the smooth road (e.g., 0.8 to 1.0).

In this case, a ratio of $\dot{\psi}$ to $\dot{\psi}_m$ and a ratio of \dot{y} to \dot{y}_m are calculated by equations (11), (12), (14), and (15), and the friction value can be reduced into equation (16) or (17) below :

$$\mu = (\dot{\psi}/\dot{\psi}_m) \cdot S_3 / [(\dot{\psi}/\dot{\psi}_m) \cdot S_2 - S_2 + (1/\mu_m) \cdot S_3] \quad (16)$$

$$\mu = (\dot{y}/\dot{y}_m) \cdot S_6 / [(\dot{y}/\dot{y}_m) \cdot S_5 - S_5 + (1/\mu_m) \cdot S_6] \quad (17)$$

First Embodiment

An apparatus for controlling steering of wheels of a vehicle according to a first embodiment which belongs to the fifth, seventh, and ninth modes of the present invention will be described with reference to Figs. 19 to 21.

The apparatus for controlling steering of wheels of a vehicle of this embodiment is applied to an apparatus for front wheels and basically belongs to the fifth mode shown in Fig. 8. The apparatus comprises a steering sensor I, a vehicle behavior sensor II, a control means III, a driving means IV, an actuator means V, a front wheel steering mechanism V_{10} , and a vehicle velocity sensor VI.

The steering sensor I is coaxial with a steering wheel to measure a steering angle of the steering wheel, as shown in Fig. 19.

The vehicle behavior sensor II is mounted at the center of gravity of the vehicle body and comprises a yaw rate sensor II₁ for detecting the yaw rate $\dot{\psi}$ and outputting a signal representing the yaw rate $\dot{\psi}$.

5 The control means III comprises a feed forward signal operating means III₁, a feedback signal operating means III₂, a control signal operating means III₃, and a gain changing means III₄.

The feed forward signal operating means III₁ comprises: a steering angle signal circuit III₁₁ for transmitting, without modifications, an electrical signal corresponding to a steering angle δ and output from the steering sensor I; a steering angle signal operation circuit III₁₃ provided with a first coefficient circuit III₁₂ for multiplying with G_1 the signal corresponding to the steering angle δ and output from the steering sensor I; a steering angular velocity signal operation circuit III₁₆ provided with a differentiator III₁₄ for calculating a signal corresponding to a steering angular velocity $\dot{\delta}$ on the basis of the signal corresponding to the steering angle δ and output from the steering sensor I and a second coefficient circuit III₁₅ for multiplying with G_2 the signal corresponding to the steering angular velocity $\dot{\delta}$ and output from the differentiator III₁₄; and an adder III₁₇ for adding the signals output from the first and second coefficient circuits III₁₂ and III₁₅ and the signal output from the steering angle signal circuit III₁₁.

The feedback signal operating means III₂ comprises a vehicle behavior state variable signal circuit III₂₂ provided with two coefficient circuits III₂₁ and III₂₃, a primary delay filter III₂₄, and an adder III₂₅ for adding the signals output from the coefficient circuits III₂₁ and III₂₃. The primary delay filter III₂₄ outputs a signal representing a pseudo yaw angle $\hat{\psi}$ corresponding to the yaw angle ψ on the basis of the signal representing the yaw rate $\dot{\psi}$.

As shown in Fig. 20(a), in order to derive the yaw angle ψ from the yaw rate $\dot{\psi}$, the yaw angle signal is integrated by an integrator 101. However, a steady deviation may occur in the yaw angle ψ due to the influence of slight noise in the yaw rate sensor II₁. A high-pass filter 102 having an effect shown in Fig. 20(b) is connected to the output of the integrator 101 to eliminate the above-mentioned steady deviation. The arrangement in the block diagram of Fig. 20(a) can be equivalently replaced with a primary delay filter 103 and a coefficient circuit 104 as shown in Fig. 20(c). The integrator 101 and the high-pass filter 102 are replaced with the primary delay filter 103 and the coefficient circuit 104 to obtain the same effect as described above.

30 The control signal operating means III₃ comprises an adder/subtractor III₃₁ for calculating a difference or a sum of the feed forward control signal output from the feed forward signal operating means III₁ and the feedback signal output from the feedback signal operating means III₂.

The gain changing means III₄ comprises a microcomputer 200. The microcomputer 200 comprises an input port 201 for receiving a signal corresponding to the steering angle δ , a signal corresponding to the steering angular velocity $\dot{\delta}$, and a signal corresponding to the vehicle velocity u_0 ; an arithmetic and logic unit 202 for calculating an optimal gain; a memory 203 for storing optimal gains and algorithms for the arithmetic and logic unit 202; and an output port 204 for outputting an optimal gain selected by the arithmetic and logic unit 202.

40 21. The functions of the microcomputer 200 will be described in detail with reference to a flow chart in Fig.

When the driver turns on the ignition key, initialization is performed in program P1. In this initialization routine, the operating states of all sensors are detected to check their abnormalities and set the initial values therein.

45 When the initialization routine in program P1 is completed, a value of the vehicle velocity u_0 is read from the vehicle velocity sensor VI to the microcomputer 200 (P2).

The microcomputer 200 calculates a coefficient W_1 from the vehicle velocity value (P3). If the vehicle velocity is low (e.g., $u_0 < 40$ km/h), the coefficient W_1 is given as $W_1 = 1$. However, if the vehicle velocity is high (e.g., $u_0 > 120$ km/h), the coefficient W_1 is set to be $W_1 = 0$. The intermediate values of the coefficient W_1 are successively calculated by using a proper function.

50 The steering angle δ is read from the steering sensor I to the microcomputer 200 (P4). The microcomputer 200 calculates a coefficient W_2 (P5). If the steering angle is small (e.g., $|\delta| < \delta_1 = 15^\circ$), the coefficient W_2 is set to be $W_2 = 0$. However, if the steering angle is large ($|\delta| > \delta_2 = 30^\circ$), the coefficient W_2 is set to be $W_2 = 1$. The intermediate values of the coefficient W_2 are successively calculated by a proper function. The coefficient W_2 may be changed in accordance with changes in vehicle velocity u_0 . In this case, if the vehicle velocity is low, threshold values δ_1 and δ_2 of the coefficient W_2 are set to be large. However, when the vehicle velocity is high, the threshold values δ_1 and δ_2 are set to be small.

55 The microcomputer 200 then fetches the steering angular velocity $\dot{\delta}$ output from the differentiator III₁₄ in the feed forward control means III₁ (P6) and calculates a coefficient W_3 (P7). The coefficient W_3 is deter-

mined by the steering angle δ and the steering angular velocity $\dot{\delta}$ in such a manner that $W_3 = W_{31} \times W_{32}$. W_{31} is determined by the steering angle δ . If the steering angle δ is small ($|\delta| < \delta_3 = 7.5^\circ$), then $W_{31} = 0$ is established. However, if the steering angle is relatively large ($|\delta| > \delta_4 = 25^\circ$), then $W_{31} = 1$ is established. The intermediate values of the W_{31} are successively calculated by a proper function. Similarly, the coefficient W_{32} is determined by the steering angular velocity $\dot{\delta}$. If the steering angular velocity $\dot{\delta}$ is small ($|\dot{\delta}| < \dot{\delta}_1 = 15^\circ/\text{sec}$), then $W_{32} = 0$ is established. However, if the angular velocity $\dot{\delta}$ is large ($|\dot{\delta}| > \dot{\delta}_2 = 30^\circ/\text{sec}$), then $W_{32} = 1$ is established. The coefficients W_{31} and W_{32} may be changed in accordance with the changes in vehicle velocity in the same manner as in the coefficient W_2 .

The signals from the above sensors are received and the coefficients W_1 , W_2 , and W_3 are calculated as described above. Coefficients M_1 and M_2 are then calculated (P8 and P9). The coefficient M_1 is calculated by $M_1 = W_1 \times W_2$; and the coefficient M_2 is calculated by $M_2 = W_1 \times W_3$.

A truth value M is calculated using the coefficients M_1 and M_2 (P10). In this case, a larger one of the coefficients M_1 and M_2 is used.

Optimal gains G_1 , G_2 , G_3 , and G_4 obtained on the basis of the truth value M are output to the coefficient circuits III_{12} , III_{13} , III_{21} , and III_{22} (P11), respectively. The optical gains are calculated as follows :

$$G_i = (1 - M) \times G_{i0} + M \times G_{i1}$$

wherein G_{i0} and G_{i1} are optimal gains for $M = 0$ and $M = 1$ where i represents 1, 2, 3, or 4.

After program P11 is executed, the flow returns to program P2, and the above operations are repeated.

The memory 203 stores optimal gains G_{10} , G_{20} , G_{30} , and G_{40} obtained for $M = 0$, optimal gains G_{11} , G_{21} , G_{31} , and G_{41} obtained for $M = 1$, and programs P1 to P11 in addition to the values δ_1 , δ_2 , δ_3 , δ_4 , $\dot{\delta}_1$, and $\dot{\delta}_2$.

The driving means IV comprises an amplifier IV_1 for receiving the steering control signal output from the control means III, i.e., the signal corresponding to the front wheel steering angle, and converting the steering control signal into an actuator drive signal.

The actuator means V serves to convert the actuator drive signal from the driving means IV into a front wheel steering angle and comprises a hydraulic piston V_1 , an oil-assisted mechanism V_2 , a stepping motor V_3 , and a gear box V_4 .

The front wheel steering mechanism V_{10} comprises front wheels 511, steering linkages 512, and rods 513.

The oil-assisted mechanism V_2 comprises : a hydraulic pump 501 ; a relief valve 502 for maintaining an oil pressure at a predetermined pressure ; an accumulator 503 for suppressing variations in oil pressure in the hydraulic pump 501 ; a servo valve 504 for determining a direction for supplying an oil to the hydraulic piston V_1 ; an oil supply path 505 for supplying the oil pressure to the hydraulic piston V_1 ; an oil return path 506 for returning the oil discharged from the hydraulic piston V_1 and the oil leaking from the relief valve 502 ; and an oil tank 507 for storing the oil used in the oil-assisted mechanism.

The front wheels 511 are rotatably supported on the vehicle body through the steering linkages 512, respectively. The steering linkages 512 are coupled through the rods 513 and the hydraulic piston V_1 . The stepping motor V_3 is controlled by a signal corresponding to the front wheel steering angle from the driving means IV. The stepping motor V_3 drives the servo valve 504 and also drives the rods 513 through the gear box V_4 in the right-and-left direction. By these mechanisms, the stepping motor V_3 drives the rods 513 in the right-and-left direction in response to the signal from the driving means IV. At the same time, the stepping motor V_3 drives the servo valve 504 to cause it to supply the compressed oil from the oil supply path 505 to one chamber of the hydraulic piston V_1 . At the same time, the stepping motor V_3 causes the other chamber to communicate with the oil tank 507 through the oil return path 506. Therefore, the hydraulic piston V_1 is driven to assist the force acting on the stepping motor V_3 , and the front wheels 511 can be steered in the right or left direction.

The vehicle velocity sensor VI is mounted on an output shaft of a vehicle transmission. The sensor VI detects the vehicle velocity u_0 and outputs a signal representing the vehicle velocity u_0 .

The functions of the first embodiment having the above arrangement will be described below.

The outputs from the steering sensor I for measuring the steering angle of the steering wheel and the vehicle behavior sensor II provided with the yaw rate sensor II_1 for outputting the yaw rate $\dot{\psi}$ are input to the feed forward signal operating means III_1 and the feedback signal operating means III_2 in the control means III.

The feed forward signal operating means III_1 classifies the input signals into the signal corresponding to the steering angle δ and the signal corresponding to the steering angular velocity $\dot{\delta}$ through the differentiator III_{14} . These signals are input to the input port 201 in the gain changing means III_4 together with the vehicle velocity u_0 from the vehicle velocity sensor VI mounted on the transmission.

The feedback signal operating means III₂ classifies the input signals into the signal corresponding to the yaw rate $\dot{\psi}$ and the signal representing the pseudo yaw angle $\hat{\psi}$ through the primary delay filter III₂₄.

The input port 201 in the gain changing means III₄ determines the vehicle state on the basis of the inputs. More specifically, the degree of the vehicle velocity u_0 , the degree of the steering angle δ , and the degree of the steering angular velocity $\dot{\delta}$ are replaced with the coefficients W_1 , W_2 and W_3 which are continuously changed between 0 and 1 so as to correspond to the human evaluation values in accordance with the following logical sequences :

(I) If the vehicle velocity u_0 is high, stability is improved.

(II) If the vehicle velocity u_0 is not high, the following conditions are applied.

(III) If the absolute value $|\delta|$ of the steering angle is large, the controllability is shortened.

(IV) If the absolute value $|\delta|$ of the steering angle is small, stability is improved.

(V) If the absolute value $|\delta|$ of the steering angle is relatively large and the absolute value $|\dot{\delta}|$ of the steering angular velocity is also large, the controllability is shortened.

(VI) If the absolute value $|\delta|$ of the steering angle is relatively large and the absolute value $|\dot{\delta}|$ of the steering angular velocity is small, stability is improved.

The "improvement of stability" here indicates that the vehicle can maintain the proper route even if disturbance such as a side wind acts on the vehicle. The "shortening of the controllability" here indicates that the vehicle quickly responds to the driver's operation so as to, e.g., immediately change the lane when the driver wants to detour an obstacle.

The logical sequences (I) to (VI) are performed by calculations $M_1 = W_1 \times W_2$ and $M_2 = W_1 \times W_3$. A contribution index, i.e., the truth value M is determined by using the maximum values of the coefficients M_1 and M_2 . Optimal gain values are then determined in accordance with the truth value M .

The optimal gains G_{10} , G_{20} , G_{30} , and G_{40} for truth value $M = 0$ and the optimal gains G_{11} , G_{21} , G_{31} , and G_{41} for truth value $M = 1$ are prestored in the memory 203. The values of the optimal gains calculated by the arithmetic and logic unit 202 are output at the output port 204.

The optimal gain outputs G_i ($i = 1$ to 4) from the output port 204 in the gain changing means III₄ are input to the first coefficient circuit III₁₂ and the second coefficient circuit III₁₅ in the feed forward signal operating means III₁ and the two coefficient circuits III₂₁ and III₂₃ in the feedback signal operating means III₂. Therefore, optimal gains can be provided to the signals δ , $\dot{\delta}$, ψ , and $\hat{\psi}$.

The adder III₁₇ in the feed forward signal operating means III₁ adds the steering angle signal δ , a signal $G_1 \cdot \delta$ obtained by multiplying the steering angle signal with the optimal gain G_1 , and a signal $G_2 \cdot \dot{\delta}$ obtained by the differential value signal $\dot{\delta}$ of the steering angle with the optimal gain G_2 to output a feed forward signal $\delta + G_1 \cdot \delta + G_2 \cdot \dot{\delta}$ to the control signal operating means III₃.

The adder III₂₅ in the feedback signal operating means III₂ adds a signal $G_3 \cdot \dot{\psi}$ obtained by multiplying the yaw rate signal $\dot{\psi}$ with the optimal gain G_3 , and a signal $G_4 \cdot \hat{\psi}$ obtained by multiplying the pseudo yaw angle signal $\hat{\psi}$ with the optimal gain G_4 to output a feedback signal $G_3 \cdot \dot{\psi} + G_4 \cdot \hat{\psi}$ to the control signal operating means III₃.

The driving means IV drives the following operation control signal u to drive the actuator means V :

$$u = \delta + G_1 \cdot \delta + G_2 \cdot \dot{\delta} + G_3 \cdot \dot{\psi} + G_4 \cdot \hat{\psi}$$

Therefore, the front wheel steering mechanism V₁₀ is driven to perform predetermined steering control.

With the above operations, the front wheels 511 are steered by a constant multiple (i.e., a gear ratio of the gear box V₄) of the steering control signal obtained by adding the feed forward signal derived from the steering wheel steering angle δ and the steering velocity $\dot{\delta}$ to the feedback signal derived from the vehicle yaw rate $\dot{\psi}$.

The vehicle mounted with the apparatus for controlling steering of wheels of the vehicle immediately responds to steering of the steering wheel when the driver quickly turns the steering wheel or turns it with a large steering angle at a relatively low vehicle velocity since the values of the gains G_1 , G_2 , G_3 , and G_4 output to the coefficient circuits III₁₂, III₁₅, III₂₁, and III₂₃ in the control means III are adjusted to those corresponding to $M \approx 1$. When the vehicle velocity is relatively high and an external force caused by a side wind, a rut, a bump, or the like acts on the vehicle, the driver does not instantaneously turn the steering wheel. In this state, since the gains G_1 , G_2 , G_3 , and G_4 are controlled by the gain changing means III such that the truth value M is almost zero, vehicle stability can be improved and the front wheels are driven to automatically cancel disturbance.

When the response time is shortened at a relatively high velocity during quick turning of the steering wheel, the driver cannot often control the vehicle. In order to prevent this, the values of the gains G_1 , G_2 , G_3 , and G_4 are controlled such that the truth value M is almost zero. Therefore, the vehicle can change the

direction safely.

In the vehicle mounted with the apparatus of this embodiment, optimal dynamic characteristics of the vehicle are provided for the behaviors of the vehicle and steering of the steering wheel by the driver.

5 Second Embodiment

An apparatus for controlling steering of wheels of a vehicle according to a second embodiment which belongs to the sixth and seventh modes of the present invention will be described with reference to Figs. 22 and 23.

10 This apparatus is applied to the one for the front wheels and basically belongs to the sixth mode shown in Fig. 9. The apparatus comprises a steering sensor I, a vehicle behavior sensor II, a control means III, a driving means IV, an actuator means V, a vehicle velocity sensor VI, and a raindrop sensor VII.

The vehicle behavior sensor II comprises a yaw rate sensor II₁ for detecting an angular velocity around the center of the gravity of the vehicle and a lateral acceleration sensor II₂ for measuring a lateral acceleration of the vehicle, as shown in Fig. 22.

The control means III comprises a feed forward signal operating means III₁, a feedback signal operating means III₂, a control signal operating means III₃, and a gain changing means III₄.

The feed forward signal operating means III₁ comprises : a steering angle signal circuit III₁₁ for transmitting an electrical signal corresponding to a steering angle δ and output from the steering sensor I ; a steering angle signal operation circuit III₁₃ provided with a first coefficient circuit III₁₂ for multiplying with G_1 a signal corresponding to the steering angle δ and output from the steering sensor I ; a steering angular velocity signal operation circuit III₁₈ provided with a differentiator III₁₄ for calculating a signal corresponding to a steering angular velocity $\dot{\delta}$ on the basis of the signal corresponding to the steering angle δ and output from the steering sensor I and a second coefficient circuit III₁₆ for multiplying with G_2 a signal corresponding to the steering angular velocity $\dot{\delta}$ and output from the differentiator III₁₄; and an adder III₁₇ for adding the signals output from the first and second coefficient circuits III₁₂ and III₁₆ and the signal output from the steering angle signal circuit III₁₁.

The feedback signal operating means III₂ comprises four coefficient circuits III₂₁, III₂₃, III₂₆, and III₂₇, primary delay filters III₂₄ and III₂₈, an integrator III₂₉, and a vehicle behavior state variable signal circuit III₂₂ provided with three adders III₂₀, III₂₅, and III₃₀.

The primary delay filter III₂₄ outputs a signal representing a pseudo yaw angle $\hat{\psi}$ corresponding to a yaw angle ψ on the basis of the signal representing the yaw rate $\dot{\psi}$. The primary delay filter III₂₈ outputs a signal representing a pseudo lateral displacement \hat{y} corresponding to the lateral displacement y on the basis of the signal corresponding to the lateral velocity \dot{y} calculated by the integrator III₂₉. The functions and effects of these primary delay filters III₂₄ and III₂₈ are the same as those in the first embodiment.

The coefficient circuits III₂₁, III₂₃, III₂₆ and III₂₇ multiply the corresponding signals with the yaw rate feedback gain G_3 , the yaw angle feedback gain G_4 , the lateral velocity feedback gain G_5 , and the lateral displacement feedback gain G_6 , respectively. The adders III₂₀, III₂₅ and III₃₀ are used to add signals output from the four coefficient circuits III₂₁, III₂₃, III₂₆ and III₂₇.

40 The control signal operating means III₃ comprises an adder/subtractor III₃₁ for calculating a difference or a sum of the signal output from the feed forward signal operating means III₁ and the signal output from the feedback signal operating means III₂.

The gain changing means III₄ comprises a microcomputer 200. The microcomputer 200 comprises : an input port 201 for receiving the signal corresponding to the steering angle δ , the signal corresponding to the steering angular velocity $\dot{\delta}$, the signal corresponding to the vehicle velocity u_0 , the signal corresponding to the yaw rate $\dot{\psi}$, the signal corresponding to the lateral acceleration \ddot{y} , and the signal corresponding to the rainfall r ; an arithmetic and logic unit 202 for discriminating the state of the vehicle on the basis of the inputs and calculating optimal gains ; a memory 203 for storing the optimal gains and an algorithm for the arithmetic and logic unit 202 ; and an output port 204 for outputting the optimal gains selected by the arithmetic and logic unit 202.

The functions of the microcomputer 200 are substantially the same as those shown in the flow chart of Fig. 21. Differences between the first and second embodiments are concentrated and described with reference to Fig. 23.

Programs P1 to P7 are the same as those in the first embodiment.

55 In program P8, the microcomputer 200 fetches an output from the raindrop sensor VII and calculates a coefficient W_4 (P9). The coefficient W_4 is determined by the rainfall r . If the rainfall is small ($r < r_1 = 1$ mm/h), then $W_4 = 1$ is established. However, if the rainfall is large ($r > r_2 = 10$ mm/h), then $W_4 = 0$ is established. The intermediate values of the rainfall are successively calculated by a proper function.

The signals of the above sensors are fetched by the microcomputer 200, and the microcomputer 200 calculates the coefficients M_1 and M_2 (P10 and P11) after calculating the coefficients W_1 , W_2 , W_3 and W_4 . The coefficient M_1 is calculated by $M_1 = W_1 \times W_2 \times W_4$; and the coefficient M_2 is calculated by $M_2 = W_1 \times W_3 \times W_4$.

5 The truth value M is calculated using the coefficients M_1 and M_2 (P12). A larger one of the coefficients M_1 and M_2 is used for the truth value M .

Optimal gains G_1 , G_2 , G_3 , and G_4 , G_5 and G_6 obtained in good outside environmental situations such as a smooth road surface are calculated using the resultant truth value M (P13). These optimal gains are calculated by the following algorithm :

10

$$G_i = (1 - M) \times G_{i0} + M \times G_{i1}$$

where G_{i0} and G_{i1} ($i = 1$ to 6) are optimal gains in good outside environmental situations for $M = 0$ and $M = 1$, respectively.

15 The optimal gains G_i ($i = 1$ to 6) can be obtained by the following control principle.

Two-degree-of-freedom motion equations of a weight m and yaw inertia moments I_z of the yaw and lateral directions are represented as follows (in this case, the vehicle is given as a two-wheel steer vehicle):

20

$$m \cdot \ddot{y} = 2(F_f + F_r) \quad (18)$$

$$I_z \cdot \ddot{\psi} = 2(a_f \cdot F_f - a_r \cdot F_r) \quad (19)$$

for

$$F_f = -c_f \{(\dot{y} - u_0 \psi + a_r \dot{\psi})/u_0 - \delta_f\}$$

$$F_r = -c_r \{(\dot{y} - u_0 \psi + a_f \dot{\psi})/u_0\}$$

25

where

a_f : the distance between the front axle of the vehicle and its center of gravity

a_r : the distance between the rear axle of the vehicle and its center of gravity

c_f : the cornering power of the front wheels of the vehicle

30

c_r : the cornering power of the rear wheels of the vehicle

F_f : the cornering force of the front wheels of the vehicle

F_r : the cornering force of the rear wheels of the vehicle

u_0 : the vehicle velocity

ψ : the yaw angle of the vehicle

35

$\dot{\psi}$: the yaw rate of the vehicle

$\ddot{\psi}$: the yaw angular acceleration

y : the lateral displacement of the vehicle

\dot{y} : the lateral velocity of the vehicle

\ddot{y} : the lateral acceleration of the vehicle

40

δ_f : the front wheel steering angle of the vehicle

The steering pattern of the driver can be given as follows :

$$\ddot{\delta}_f = f(y, \dot{y}, \psi, \dot{\psi}, \delta_f, \dot{\delta}_f) \quad (20)$$

45

When equations (18) to (20), i.e., the steering patterns of the driver, and auxiliary steering variable u of the time-serial optimal front wheel steering angle signal applied to the front wheel steering system are taken into consideration, the equations of motion are given as follows :

$$m \cdot \ddot{y} = 2(F_f + F_r + u \cdot c_f) \quad (21)$$

50

$$I_z \cdot \ddot{\psi} = 2(a_f \cdot F_f - a_r \cdot F_r + u \cdot a_f \cdot c_f) \quad (22)$$

$$\ddot{\delta}_f = f(y, \dot{y}, \psi, \dot{\psi}, \delta_f, \dot{\delta}_f, u) \quad (23)$$

Th auxiliary steering angle is given as :

55

$$\begin{aligned}
 u &= \sum_{i=1}^6 g_i \cdot x_i \\
 &= g(\dot{y}, \dot{\psi}, \psi, \dot{\delta}_F, \delta_F)
 \end{aligned}$$

5

where g_i is a contribution coefficient for giving the optimal auxiliary steering angle u , and x_i represent all possible vehicle travel state variables with the vehicle travel and the vehicle behaviors which express the motion of the vehicle. These variables include the vehicle lateral displacement, the vehicle lateral velocity, the yaw angle, the yaw rate, the steering angle of the steering wheel turned by the driver, and its steering angular velocity.

Output values from the yaw rate sensor II₁ and the lateral acceleration sensor II₂, i.e., the yaw rate $\dot{\psi}$ and the lateral acceleration \dot{y} are fetched by the microcomputer 200 (P14 and P15). The microcomputer 200 then fetches a steering control signal δ_r (P16). The yaw rate $\dot{\psi}$ and the lateral acceleration \dot{y} are divided by the steering control signal δ_r (P17 and P18), and the quotients are then compared with the steady vehicle steering gains of the actual steering angle and yaw rate and the measured lateral acceleration (P19 and P20), thus outputting coefficients N_1 and N_2 (P21 and P22). The coefficients N_1 and N_2 are inverse numbers obtained by dividing the quotients by the steady vehicle steering gains. If each coefficient N_1 and N_2 exceeds 1.5, it is set to be 1.5. The coefficients N_1 and N_2 are multiplied with the gains G_1 to G_8 and the products are respectively output to the coefficient circuits III₁₂, III₁₃, III₂₁, III₂₂, III₂₃, and III₂₄ (P23 and P24).

After program P24 is executed, the flow returns to program P2, and the above operations are repeated.

Optimal gains G_{10} , G_{20} , G_{30} , G_{40} , G_{50} and G_{60} for $M = 0$, optimal gains G_{11} , G_{21} , G_{31} , G_{41} , G_{51} and G_{61} for $M = 1$, and programs P1 to P22 are stored in the memory 203 in addition to the signals δ_1 , δ_2 , δ_3 , δ_4 , $\dot{\delta}_1$, $\dot{\delta}_2$, r_1 , r_2 , the measured steering angle, the yaw rate, and the steady vehicle steering gains of the measured steering angle and the measured lateral acceleration.

The driving means IV comprises a subtracter IV₁ for calculating a difference between the steering control signal output from the control means III, i.e., the signal corresponding to the front wheel steering angle, and a signal output from a rod displacement meter 514 included in the actuator means V, and an amplifier IV₂ for converting the signal output from the subtracter IV₁ into a signal to be supplied to the servo valve 525 included in the actuator means V.

The actuator means V converts the signal from the driving means IV into a front wheel steering angle and comprises a front wheel steering mechanism V₁₀ and an electrohydraulic control mechanism V₂₀.

The front wheel steering mechanism V₁₀ comprises front wheels 511, steering linkages 512, rods 513, and the rod displacement meter 514.

The electrohydraulic control mechanism V₂₀ comprises a hydraulic pump 521, a relief valve 522 for maintaining an oil pressure at a predetermined pressure, an accumulator 523 for suppressing variations in oil pressure in the hydraulic pump 521, a hydraulic piston 524, a servo valve 525 for determining a direction for supplying an oil to the hydraulic piston 524, an oil supply path 526 for supplying the oil pressure to the hydraulic piston 524, an oil return path 527 for returning the oil discharged from the hydraulic piston 524 and the oil leaking from the relief valve 522, and an oil tank 528 for storing the oil to be used in the electrohydraulic control mechanism V₂₀.

The front wheels 511 are rotatably supported on the vehicle body through steering linkages 512. The steering linkages 512 are coupled through the rods 513 and the hydraulic piston 524. The servo valve 525 is controlled by a difference between the front wheel steering angle signal from the driving means IV and the output from the control means III. In other words, the servo valve 525 is controlled by a signal corresponding to the front wheel steering angle deviation. The compressed oil, which is controlled at a predetermined pressure by the hydraulic pump 521, the relief valve 522, and the accumulator 523 is supplied to one chamber of the hydraulic piston 524 through the oil supply path 526 by the servo valve. The other chamber communicates with the oil tank 528 through the oil return path 527, thereby driving the hydraulic piston 524. Therefore, the front wheels 511 can be steered in the right or left direction through the rods 513 and the steering linkages 512.

The vehicle velocity sensor VI is mounted on the output shaft of the transmission. This sensor VI detects the vehicle velocity u_0 and outputs a signal representing the vehicle velocity u_0 .

The raindrop sensor VII is located in the front portion of the vehicle body. This sensor VII detects raindrops or a humidity and outputs a signal representing whether the road is slippery.

The function and the effect of this embodiment having the above arrangement will be described below.

The steering sensor I and the yaw rate sensor II₁ included in the vehicle behavior sensor II are substantially the same as those in the first embodiment. However, the vehicle behavior sensor II also includes

a lateral acceleration sensor II_2 in addition to the yaw rate sensor II_1 . The lateral acceleration sensor II_2 is used to measure a lateral acceleration of the vehicle.

The input port 201 in the gain changing means III_4 receives a signal corresponding to the yaw rate $\dot{\psi}$ and output from the yaw rate sensor II_1 in the vehicle behavior sensor II, a signal corresponding to the lateral acceleration \ddot{y} and output from the lateral acceleration sensor II_2 in the vehicle behavior sensor II, and a signal corresponding to the rainfall r and output from the raindrop sensor VII, in addition to the signals used in the first embodiment, i.e., the signal corresponding to the steering angle δ , the signal corresponding to the steering angular velocity $\dot{\delta}$, and the signal corresponding to the vehicle velocity u_0 .

The feedback signal operating means III_2 divides the input data into the signal corresponding to the yaw rate $\dot{\psi}$, a signal representing a pseudo yaw angle $\hat{\psi}$ through the primary delay filter III_{24} , a signal representing the lateral velocity \dot{y} through the integrator III_{25} on the basis of the signal corresponding to the lateral acceleration \ddot{y} , and a signal representing a pseudo lateral displacement \hat{y} through the primary delay filter III_{28} .

The input port 201 of the gain changing means III_4 determines the state of the vehicle on the basis of the input signals. The input port 201 replaces the input signals into the coefficients W_1 , W_2 , W_3 , and W_4 which continuously change between 0 and 1 so as to correspond to human evaluation values representing the degree of the vehicle velocity u_0 , the degree of the steering angle δ , the degree of the steering angular velocity $\dot{\delta}$, and the degree of the rainfall r in the following logical sequences :

- (I) If the vehicle velocity u_0 is high or the rainfall r is large, stability is improved.
- (II) If the vehicle velocity u_0 is not high and the rainfall r is small, the following rules are applied.
- (III) If the absolute value $|\delta|$ of the steering angle is large, the response time is shortened.
- (IV) If the absolute value $|\delta|$ of the steering angle is small, stability is improved.
- (V) If the absolute value $|\delta|$ of the steering angle is relatively large and the absolute value $|\dot{\delta}|$ of the steering angular velocity is large, the response time is shortened.
- (VI) If the absolute value $|\delta|$ of the steering angle is relatively large and the absolute value $|\dot{\delta}|$ of the steering angular velocity is small, stability is improved.

The "improvement of stability" here indicates that the vehicle can maintain the proper route even if disturbance such as a side wind acts on the vehicle. The "shortening of the response time" here indicates that the vehicle quickly responds to the driver's operation so as to, e.g., immediately change the lane when the driver wants to detour an obstacle.

The logical sequences (I) to (VI) are performed by calculations $M_1 = W_1 \times W_2 \times W_4$ and $M_2 = W_1 \times W_3 \times W_4$. A contribution index, i.e., the truth value M is determined by using the maximum values of the coefficients M_1 and M_2 . Optimal gain values are then determined in accordance with the truth value M .

The optimal gains G_{10} , G_{20} , G_{30} , G_{40} , G_{50} and G_{60} for truth value $M = 0$ and the optimal gains G_{11} , G_{21} , G_{31} , G_{41} , G_{51} and G_{61} for truth value $M = 1$ are prestored in the memory 203. The optimal gain values are calculated by the arithmetic and logic unit 202.

The coefficients N_1 and N_2 are calculated to weight the optimal gain values calculated by the arithmetic and logic unit 202 so as to set the response characteristics of the vehicle for the variables representing vehicle behaviors constant. The coefficients N_1 and N_2 are multiplied with the calculated optimal gain values to keep the vehicle response time for the steering wheel angle constant.

The calculated optimal gain values as the optimal gain outputs G_i ($i = 1$ to 6) from the output port 204 in the gain changing means III_4 are input to the first and second coefficient circuits III_{12} and III_{15} in the feed forward signal operating means III_1 and the four coefficient circuits III_{21} , III_{23} , III_{26} and III_{27} in the feedback signal operating means III_2 . The coefficient circuits provides optimal gains for the signals δ , $\dot{\delta}$, $\dot{\psi}$, $\hat{\psi}$, \dot{y} and \hat{y} , respectively.

The feed forward signal operating means III_1 outputs the feed forward signal $\delta + G_1 \cdot \delta + G_2 \cdot \dot{\delta}$ to the control signal operating means III_3 in the same manner as in the first embodiment.

The adder III_{25} in the feedback signal operating means III_2 adds a signal $G_3 \cdot \dot{\psi}$ obtained by multiplying the yaw rate signal $\dot{\psi}$ with the optimal gain G_3 , a signal $G_4 \cdot \hat{\psi}$ obtained by multiplying the pseudo yaw angle signal $\hat{\psi}$ with the optimal gain G_4 , a signal $G_5 \cdot \dot{y}$ obtained by multiplying the lateral acceleration signal \dot{y} with the optimal gain G_5 , and a signal $G_6 \cdot \hat{y}$ obtained by multiplying the pseudo lateral displacement signal \hat{y} with the optimal gain G_6 and outputs the feedback signal $G_3 \cdot \dot{\psi} + G_4 \cdot \hat{\psi} + G_5 \cdot \dot{y} + G_6 \cdot \hat{y}$ to the control signal operating means III_3 .

The driving means IV drives the actuator V in accordance with the signal δ_f from the control signal operating means III_3 :

$$\delta_f = \delta + G_1 \cdot \delta + G_2 \cdot \dot{\delta} + G_3 \cdot \dot{\psi} + G_4 \cdot \hat{\psi} + G_5 \cdot \dot{y} + G_6 \cdot \hat{y}$$

The actuator V drives the front wheel steering mechanism V_1 to perform predetermined steering control.

The variables representing the vehicle travel and the vehicle behaviors are instantaneously detected to provide optimal front wheel steering control angle δ_r and the coefficients g_i are determined by contribution degrees. An instantaneous state feedback control system including the factors of the driver can be provided.

5 Therefore, the driver can perform optimal steering wheel angle control.

Since signals input to the control means include the rainfall r from the raindrop sensor VII, the yaw rate $\dot{\psi}$, and the lateral acceleration \ddot{y} . When the road is slippery, an auxiliary steering angle may be added to the above value. The response and stability characteristics of the vehicle can be adjusted without imposing a metal load on the driver, and optimal steering angle control can be performed so as to satisfy the weather and road conditions. and optimal steering angle control can be performed so as to satisfy the weather and road conditions.

Modification

15 The apparatuses for controlling steering of wheels of a vehicle are applied to the apparatuses for controlling steering of front wheels of the vehicle in the first and second embodiments. However, an apparatus for controlling steering of wheels of a vehicle may be applied to an apparatus for controlling steering of rear wheels of a vehicle.

20 The apparatus for controlling steering of wheels of a vehicle according to the first embodiment which belongs to the fifth and seventh modes is applied to an apparatus for controlling steering of rear wheels of a vehicle. This modification will be described with reference to Fig. 24.

Differences between the modification and the first embodiment are concentrated.

A driving means IV comprises an amplifier IV_1 for receiving the steering control signal output from the control means III, i.e., a signal corresponding to a rear wheel steering angle, and for converting it into an actuator drive signal.

25 An actuator means V converts the signal output from the driving means IV into a rear wheel steering angle and comprises a rear wheel steering mechanism V_{30} , an oil-assisted mechanism V_2 , and a stepping motor V_3 .

30 The rear wheel steering mechanism V_{30} comprises rear wheels 531, knuckles 532, knuckle arms 533, rods 534, a gear box 535 and a hydraulic piston 536.

The oil-assisted mechanism V_2 comprises a hydraulic pump 521, a relief valve 522 for maintaining an oil pressure at a predetermined pressure, an accumulator 523 for suppressing variations in oil pressure in the hydraulic pump 521, a servo valve 525 for determining a direction for supplying an oil to the hydraulic piston 536, an oil supply path 526 for supplying the oil pressure to the hydraulic piston 536, an oil return path 527 for returning the oil discharged from the hydraulic piston 536 and the oil leaking from the relief valve 522, and an oil tank 528 for storing the oil to be used in the oil-assisted mechanism.

40 The rear wheels 531 are rotatably supported on the vehicle body through knuckles 532. The knuckle arms 533 are coupled through the rods 534 and the hydraulic piston 536. The stepping motor V_3 is operated by a signal corresponding to the rear wheel steering angle and output from the driving means IV. The stepping motor V_3 drives the servo valve 525 and also drives the rods 534 through the gear box 535 in the right-and-left direction. By these mechanisms, the stepping motor V_3 drives the rods 534 in the right or left direction in response to the signal from the driving means IV. The compressed oil from the oil supply path 526 is supplied to one chamber of the hydraulic piston 536 upon operation of the servo valve 525. The other chamber communicates with the oil tank 528 through the oil return path 527. The hydraulic piston 536 is driven to assist the power acting on the stepping motor V_3 . Therefore, the rear wheels 531 can be steered in the right or left direction.

45 A front wheel steering mechanism V_{10} comprises front wheels 511, steering linkages 512, rods 513, a rack 515, and a pinion 516. The front wheels 511 are rotatably supported on the vehicle body through the steering linkages 512. The steering linkages 512 are coupled through the rods 513 and the rack 515. When the driver turns the steering wheel, the pinion 516 is rotated. The rotational movement of the pinion 516 is converted into linear movement by the rack 515. The rods 513 can be moved in the right or left direction, thereby steering the front wheels 511 through the steering linkages 512 in the right or left direction.

50 The vehicle velocity sensor VI is mounted on the output shaft of the transmission. This sensor VI detects the vehicle velocity u_0 and outputs a signal representing the vehicle velocity u_0 .

55 With the above operations, the rear wheels 511 are steered in accordance with a steering control signal obtained by calculating a difference or a sum of the feed forward signal derived from the steering angle δ and the steering angular velocity $\dot{\delta}$, and the feedback signal derived from the vehicle yaw rate $\dot{\psi}$.

In the apparatus for controlling steering of the rear wheels of the vehicle, gains G_{10} , G_{20} , and G_{30} for

$M = 0$ and gains G_{11} , G_{21} , and G_{31} for $M = 1$, which are stored in the microcomputer 200 in the control means III, are different from those in the first embodiment. However, the same algorithms can be used, and optimal rear wheel steering angles corresponding to various states can be generated.

Similarly, the apparatus of the second embodiment can also be applied to an apparatus for controlling steering of rear wheels of a vehicle.

The apparatus may be used for both the front and rear wheels, although such an application is not described above.

If four-wheel drive control is performed, two sets of gain values for the front and rear wheels must be stored in the microcomputer 200 in the control means III, and the apparatus of the first or second embodiment is combined with that of the modification.

Third Embodiment

An apparatus for controlling steering of wheels of a vehicle according to a third embodiment which belongs to the eleventh mode of the present invention will be described with reference to Figs. 25 and 26.

An apparatus for controlling steering of wheels of a vehicle according to this embodiment is applied to an apparatus for controlling steering of front wheels of the vehicle. This apparatus basically belongs to the eleventh mode shown in Fig. 14 and comprises a steering sensor I, a vehicle behavior sensor II, a control means III, a driving means IV, an actuator means V, and a vehicle state detection sensor VI.

The steering sensor I is coaxial with the steering wheel to measure a steering angle of the steering wheel, as shown in Fig. 25.

The vehicle behavior sensor II comprises a yaw rate sensor II₁ for detecting a yaw rate $\dot{\psi}$ of the vehicle and outputting a signal representing the yaw rate $\dot{\psi}$, and a lateral acceleration sensor II₂ for detecting a lateral acceleration \ddot{y} of the vehicle and outputting a signal representing the lateral acceleration \ddot{y} . The vehicle behavior sensor II is mounted at the center of gravity of the vehicle.

The control means III comprises a feed forward signal operating means III₁, a feedback signal operating means III₂, a control signal operating means III₃, and a gain changing means III₄.

The feed forward signal operating means III₁ comprises: a steering angle signal circuit III₁₁ for transmitting, without modifications, an electrical signal corresponding to the steering angle δ and output from the steering sensor I; a steering angle signal operating circuit III₁₃ provided with a first coefficient circuit III₁₂ for multiplying with G_1 the signal corresponding to the steering angle δ and output from the steering sensor I; a steering angular velocity signal operating circuit III₁₈ provided with a differentiator III₁₄ for calculating a signal corresponding to a steering angular velocity $\dot{\delta}$ on the basis of the signal corresponding to the steering angle δ and output from the steering sensor I and a second coefficient circuit III₁₅ for multiplying with G_2 the signal corresponding to the steering angular velocity $\dot{\delta}$ and output from the differentiator III₁₄; and an adder III₁₇ for adding the signals output from the first and second coefficient circuits III₁₂ and III₁₅ and the signal output from the steering angle signal circuit III₁₁.

The feedback signal operating means III₂ comprises a vehicle behavior state variable signal circuit III₂₂ provided with four coefficient circuits III₂₁, III₂₃, III₂₆, and III₂₇, primary delay filters III₂₄, III₂₈, and III₂₉, an adder III₂₅ for adding the signals output from the coefficient circuits III₂₁ and III₂₃, an adder III₃₀ for adding the signals output from the coefficient circuits III₂₆ and III₂₇, and an adder III₂₀ for adding the signals output from the adders III₂₅ and III₃₀.

The primary delay filter III₂₄ outputs a pseudo yaw angle $\hat{\psi}$ corresponding to a yaw angle signal ψ on the basis of the yaw rate signal $\dot{\psi}$ from the yaw rate sensor II₁. The primary delay filter III₂₉ outputs a pseudo lateral velocity $\hat{\dot{y}}$ corresponding to the lateral velocity \dot{y} on the basis of the lateral acceleration signal from the lateral acceleration sensor II₂. The primary delay filter III₂₈ outputs a pseudo lateral displacement \hat{y} corresponding to the lateral displacement y on the basis of the pseudo lateral velocity signal $\hat{\dot{y}}$.

The control signal operating means III₃ comprises an adder/subtractor III₃₁ for calculating a difference or a sum of a feed forward control signal output from the feed forward signal operating means III₁ and a feedback signal output from the feedback signal operating means III₂.

The gain changing means III₄ comprises a microcomputer 200. The microcomputer 200 comprises: an input port 201 for receiving the signal corresponding to the yaw rate $\dot{\psi}$, the signal corresponding to the vehicle velocity u_0 , and the signal corresponding to the steering control signal as an output from the adder/subtractor III₃₁; an arithmetic and logic unit 202 for estimating the variables representing the vehicle behaviors and friction μ between the vehicle wheels and the road surface and for calculating optimal gains as a result of estimation; a memory 203 for storing algorithms for and operation results of the arithmetic and logic unit 202 and vehicle specifications; and an output port 204 for outputting optimal gains selected by the arithmetic and logic unit 202.

The functions of the microcomputer 200 will be described in detail with reference to a flow chart in Fig. 26.

When the driver turns on the ignition key, the programs in the microcomputer 200 are started, and initialization is performed (P1). In the initialization routine P1, hardware such as an A/D converter and a D/A converter and software such as control parameters are initialized.

When initialization routine P1 is completed, the yaw rate $\dot{\psi}$ from the vehicle behavior sensor 11, the steering control signal as an output from the adder/subtractor 113₁, and the vehicle velocity u_0 from the vehicle state detection sensor VI are fetched by the microcomputer 200 through the A/D converter (P2).

Coefficients (equations (7) and (8) of a yaw rate estimation model, i.e., equation (8) are obtained on the basis of the vehicle velocity u_0 and the vehicle specifications. The coefficients and the steering control signal as an output from the adder/subtractor 113₁ are used to solve equation (8), thereby obtaining an estimated value $\dot{\psi}_m$ of the vehicle yaw rate (P3).

The microcomputer 200 calculates the change points (e.g., the peak values of the signals and their phases) of the corresponding signals $\dot{\psi}$ and $\dot{\psi}_m$ which are respectively the yaw rate $\dot{\psi}$ input from the A/D converter and the estimated yaw rate value $\dot{\psi}_m$ obtained in program P3 (these signals are generated by the given steering control signal) (P4).

The friction value μ is estimated by program P5 by the peak value phase difference obtained in program P4. More specifically, the peak value phase difference obtained in program P4 exceeds a given threshold value (e.g., 90°), the friction value μ is determined to be small, and the flow advances to the next step. However, the peak value phase difference is smaller than the threshold value, a peak ratio $\dot{\psi}/\dot{\psi}_m$ is calculated. The coefficients of the μ estimation equation (16) are estimated by equations (7) and (13) using the vehicle specifications and the vehicle velocity u_0 . Equation (16) is solved using the coefficients and the peak ratio to estimate μ .

Optimal coefficients for the μ value estimated in program P5 and the vehicle velocity u_0 are determined and are output to the coefficient circuits 111₁₂, 111₁₅, 111₂₁, 111₂₃, 111₂₅, and 111₂₇ (P6). The flow then returns to program P2.

The driving means IV comprises a subtractor IV₁ for calculating a difference between the steering control signal output from the control means III, i.e., the signal corresponding to the front wheel steering angle and the signal output from a rod displacement meter 514 included in the actuator means V, and an amplifier IV₂ for converting the difference signal into a signal to be output to the servo valve 525 included in the actuator means V.

The actuator means V changes the signal from the driving means IV into a front wheel steering angle and comprises a front wheel steering mechanism V₁₀ and an electrohydraulic control mechanism V₂₀.

The front wheel steering mechanism V₁₀ comprises front wheels 511, steering linkages 512, rods 513, and the rod displacement meter 514.

The electrohydraulic control mechanism V₂₀ comprises a hydraulic pump 521, a relief valve 522 for maintaining an oil pressure at a predetermined pressure, an accumulator 523 for suppressing variations in oil pressure in the hydraulic pump 521, a hydraulic piston 524, a servo valve 525 for determining a direction for supplying an oil to the hydraulic piston 524, an oil supply path 526 for supplying the oil pressure to the hydraulic piston 524, an oil return path 527 for returning the oil discharged from the hydraulic piston 524 and the oil leaking from the relief valve 522, and an oil tank 528 for storing the oil to be used in the electrohydraulic control mechanism V₂₀.

The front wheels 511 are rotatably supported on the vehicle body through the steering linkages 512. The steering linkages 512 are coupled through the rods 513 and the hydraulic piston 524. The servo valve 525 is controlled by a signal corresponding to a difference between the front wheel steering angle signal from the driving means IV and the output from the control means III. In other words, the servo valve 525 is controlled by the front wheel steering angle deviation signal. The compressed oil, which is controlled at a predetermined pressure by the hydraulic pump 521, the relief valve 522, and the accumulator 523 is supplied to one chamber of the hydraulic piston 524 through the oil supply path 526 by the servo valve. The other chamber communicates with the oil tank 528 through the oil return path 527 to drive the hydraulic piston 524. The front wheels 511 can be steered in the right or left direction through the rods 513 and the steering linkages 512.

The vehicle state detection sensor VI comprises a vehicle velocity sensor mounted on the output shaft of the transmission. The vehicle velocity sensor detects the vehicle velocity u_0 and outputs a signal representing the vehicle velocity u_0 .

The function and the effect of this embodiment having the above arrangement will be described below.

The outputs from the steering sensor I for measuring the steering angle of the steering wheel and the vehicle behavior sensor II provided with the yaw rate sensor for outputting the yaw rate $\dot{\psi}$ and the lateral

acceleration sensor II₂ for measuring a lateral acceleration of the vehicle are input to the feed forward signal operating means III₁ and the feedback signal operating means III₂ in the control means III.

The feed forward signal operating means III₁ divides the input signals into the signal corresponding to the steering angle δ , and the signal corresponding to the steering angular velocity $\dot{\delta}$ through the differentiator III₁₄.

The feedback signal operating means III₂ divides the input signals into the signal corresponding to the yaw rate $\dot{\psi}$, a signal representing a pseudo yaw angle $\hat{\psi}$ through the primary delay filter III₂₄, a signal representing a pseudo lateral velocity \hat{y} through the primary delay filter III₂₅ on the basis of the signal corresponding to the lateral acceleration \ddot{y} , and a signal representing a pseudo lateral displacement \hat{y} through the primary delay filter III₂₆.

The input port 201 in the gain changing means III₄ receives the signal corresponding to the yaw rate $\dot{\psi}$ and output from the yaw rate sensor II₁ in the vehicle behavior sensor and the signal corresponding to the lateral acceleration \ddot{y} and output from the lateral acceleration sensor II₂ in addition to the signal corresponding to the steering control signal and output from the adder/subtractor III₃, and the signal corresponding to the vehicle velocity u_0 .

The gain changing means III₄ estimates the yaw rate of the vehicle on the basis of the input signals, compares the estimated value with the peak value of the actual yaw rate to estimate μ , and calculates optimal gains corresponding to the current vehicle states by using the estimated μ value and the vehicle velocity u_0 .

The calculated optimal gain values as the optimal gain outputs G_i ($i = 1$ to 6) from the output port 204 in the gain changing means III₄ are input to the first and second coefficient circuits III₁₂ and III₁₅ in the feed forward signal operating means III₁ and the four coefficient circuits III₂₁, III₂₃, III₂₆, and III₂₇ in the feedback signal operating means III₂. Therefore, the optimal gains for the signals δ , $\dot{\delta}$, $\dot{\psi}$, $\hat{\psi}$, \hat{y} , and \ddot{y} can be provided.

The adder III₁₇ in the feed forward signal operating means III₁ adds a signal $G_1 \cdot \delta$ obtained by multiplying the steering angle signal δ with the optimal gain G_1 and a signal $G_2 \cdot \dot{\delta}$ obtained by multiplying the differential value signal $\dot{\delta}$ of the steering angle with the optimal gain G_2 and outputs a feed forward signal $\delta + G_1 \cdot \delta + G_2 \cdot \dot{\delta}$ to the control signal operating means III₃.

The adder III₂₅ in the feedback signal operating means III₂ adds a signal $G_3 \cdot \dot{\psi}$ obtained by multiplying the yaw rate signal $\dot{\psi}$ with the optimal gain G_3 , a signal $G_4 \cdot \hat{\psi}$ obtained by multiplying the pseudo yaw angle signal $\hat{\psi}$ with the optimal gain G_4 , a signal $G_5 \cdot \hat{y}$ obtained by multiplying the pseudo lateral velocity signal \hat{y} with the optimal gain G_5 , and a signal $G_6 \cdot \ddot{y}$ obtained by multiplying the pseudo lateral displacement signal \ddot{y} with the optimal gain G_6 and outputs a feedback signal $G_3 \cdot \dot{\psi} + G_4 \cdot \hat{\psi} + G_5 \cdot \hat{y} + G_6 \cdot \ddot{y}$ to the control signal operating means III₃.

The driving means IV drives the actuator means V in accordance with the steering control signal δ_r from the control signal operating means III₃:

$$\delta_r = \delta + G_1 \cdot \delta + G_2 \cdot \dot{\delta} + G_3 \cdot \dot{\psi} + G_4 \cdot \hat{\psi} + G_5 \cdot \hat{y} + G_6 \cdot \ddot{y}$$

The actuator V drives the front wheel steering mechanism V₁₀ to perform predetermined steering control.

The optimal front wheel steering control angles δ_r instantaneously detect the variables representing the vehicle travel and the vehicle behaviors to determine coefficients G_i according to the degrees of contribution. A feedback control system for instantaneous states including the factors of the driver can be arranged to perform optimal steering angle control for the vehicle driven by the driver. At the same time, the coefficients G_i ($i = 1, 2$ to 6) are determined by the estimated μ value and the vehicle velocity u_0 after the friction value μ between the vehicle wheels and the road surface is estimated during steady travelling of the vehicle. For this reason, an auxiliary steering angle may be added in an abnormal state, for example, a slippery road. Even if the driver does not notice changes in vehicle wheels or the road surface, vehicle controllability and stability can be automatically controlled, thereby achieving optimal steering angle control corresponding to given weather and road conditions.

Fourth Embodiment

An apparatus for controlling steering of wheels of a vehicle according to a fourth embodiment which belongs to the twelfth mode of the present invention will be described with reference to Figs. 27 to 34. Differences between the third and fourth embodiments are concentrated.

The apparatus for controlling steering of wheels of a vehicle according to the fourth embodiment is applied to an apparatus for controlling steering of front wheels of a vehicle. This apparatus basically belongs to the twelfth mode shown in Fig. 15 and comprises a steering sensor I, a vehicle behavior sensor II, a control

means III, a driving means IV, an actuator means V, and vehicle state detection sensors VI.

The vehicle behavior sensor II comprises a yaw rate sensor II₁ for detecting an angular velocity around the center of gravity of the vehicle and a lateral acceleration sensor II₂ for measuring a lateral acceleration of the vehicle, as shown in Fig. 27.

5 The sensor VI for detecting the vehicle travel state variables with the vehicle travel comprises a vehicle velocity sensor VI₀ mounted on the output shaft of the transmission to detect the vehicle velocity u_0 and output a signal representing the vehicle velocity u_0 , vehicle wheel angular velocity sensors VI_{i1} ($i = 1, 2, 3, 4$) for measuring angular velocities of the respective vehicle wheels, and load sensors VI_{i2} ($i = 1, 2, 3, 4$) for measuring loads acting on the respective vehicle wheels.

10 The control means III comprises a feed forward signal operating means III₁, a feedback signal operating means III₂, a control signal operating means III₃, and a gain changing means III₄.

The coefficient circuits III₂₁, III₂₃, III₂₆ and III₂₇ multiply the corresponding signals with a yaw rate feedback gain G_3 , a yaw angle feedback gain G_4 , a lateral velocity feedback gain G_5 and a lateral displacement feedback gain G_6 , respectively. The adders III₂₀, III₂₅ and III₃₀ are used to add the signals output from the
15 four coefficient circuits III₂₁, III₂₃, III₂₆ and III₂₇.

The control signal operating means III₃ comprises an adder/subtractor III₃₁ for calculating a difference or a sum of the signal output from the feed forward signal operating means III₁ and the signal output from the feedback signal operating means III₂.

The gain changing means III₄ comprises a microcomputer 200. The microcomputer 200 comprises : an
20 input port 201 for receiving the signal corresponding to the yaw rate $\dot{\psi}$, the signal corresponding to the vehicle velocity u_0 , the signal corresponding to each vehicle wheel angular velocity, the signal corresponding to each vehicle wheel load, and the signal corresponding to the steering control signal as an output from the adder/subtractor III₃₁; an arithmetic and logic unit 202 for estimating signals for variables representing vehicle behaviors and the μ value between the vehicle wheels and the road surface, for calculating the slip ratios of the wheels on the basis of the respective input signals, and for calculating optimal gains as a result
25 of the above estimation operations ; a memory 203 for storing vehicle specifications, and algorithms and operation results of the arithmetic and logic unit 202 ; and an output port 204 for outputting the optimal gains selected by the arithmetic and logic unit 202.

The functions of the microcomputer 200 will be described with reference to a flow chart in Fig. 28.

30 When the driver turns on the ignition key, the programs in the microcomputer 200 are started, and initialization is performed (P21). In initialization routine P21, hardware such as an A/D converter and a D/A converter and software such as control parameters are initialized.

When initialization routine P21 is completed, the microcomputer 200 fetches the yaw rate $\dot{\psi}$ from the vehicle behavior sensor, the vehicle velocity u_0 from the vehicle velocity sensor VI₀, the respective vehicle
35 wheel angular velocities from the vehicle wheel angular velocity sensors VI_{i1} ($i = 1, 2, 3, 4$), and the respective vehicle wheel loads from the load sensors VI_{i2} ($i = 1, 2, 3, 4$), and the steering control angle δ_f as an output from the adder/subtractor III₃₁ through the A/D converter (P22).

The coefficients (equations (7) and (8)) of yaw rate estimation model (8) are calculated on the basis of the vehicle velocity u_0 and the vehicle specifications. The resultant coefficients and the steering control signal as an output from the adder/subtractor III₃₁ are used to solve equation (8) to obtain an estimated value
40 $\dot{\psi}_m$ of the vehicle yaw rate (P23).

The corresponding signal change points (i.e., the peak values and their peak phase values) of the yaw rate $\dot{\psi}$ input from the A/D converter and the estimated value $\dot{\psi}_m$ obtained in program P23 are calculated (P24).

45 The friction value μ is estimated by the peak value phase difference obtained in program P24 (P25). More specifically, when the peak value phase difference obtained in program P24 exceeds a given threshold value (e.g., 90°), the microcomputer 200 determines that the friction value μ is small. In this case, the flow advances to the next step. However, if the peak value phase difference is smaller than the threshold value, a peak ratio $\dot{\psi}/\dot{\psi}_m$ is calculated. The coefficient of μ estimation equation (16) is calculated by equations (7) and (13) using the vehicle specifications and the vehicle velocity u_0 . The resultant value and the peak ratio
50 are used to solve equation (16) to estimate μ .

The slip ratio is calculated on the basis of the vehicle velocity u_0 read in program P22 and the respective vehicle wheel angular velocities (P26).

Optimal coefficients are selected from the map for the estimated μ values obtained in P25, the slip ratios calculated in P26, and the vehicle velocity u_0 . The selected optimal coefficients are output to the coefficient
55 circuits III₁₂, III₁₆, III₂₁, III₂₃, III₂₆, and III₂₇ (P27), respectively. The flow returns to P22.

The contents of P27 will be described in more detail with reference to a flow chart in Fig. 29.

When the driver turns on the ignition key, program P27 is started and various initial values are set

(P271).

The estimated μ value and the slip ratios are read (P272).

The state between the wheels and the road surface is determined (P273). More specifically, the estimated, μ value is corrected and weighted (e.g., Fig. 30), and the corrected value is classified (e.g., Fig. 31)

5 The slip ratios are corrected and weighted (e.g., Fig. 32). A smaller one of the resultant values is used as a decision value $G\mu$ between the wheels and the road surface.

The vehicle velocity u_0 is read (P274).

The vehicle velocity u_0 is classified (e.g., Fig. 33), and the resultant value serves as G_u (P275).

10 The coefficients of the coefficient circuits are determined (P276). The signal $G\mu$ as an output in P273 and the signal G_u as an output in P275 are used to calculate the coefficients with reference to the map shown in Fig. 34.

The resultant optimal coefficients are output to the corresponding coefficient circuits (P277). In this embodiment, abrupt changes in coefficients decided in P276 are prevented as follows. If a difference between the current coefficients and the updated coefficient is smaller than a maximum value of a predetermined coefficient change value, the current coefficient is replaced with the updated coefficient. However, 15 the above difference exceeds the maximum value, the coefficient updating range corresponds to the maximum value. In this case, the current coefficient is converged stepwise to an optimal coefficient. Alternatively, the updated coefficient is filtered through a stable primary delay filter which has the current coefficient as the initial value, thereby further updating the updated coefficient.

20 The arrangements of the driving means IV, the actuator means V, and the front wheel steering mechanism V_{10} are the same as those of the third embodiment.

The function and the effect of the fourth embodiment having the above arrangement will be described below.

The input port 201 in the gain changing means III₄ receives the signal corresponding to the yaw rate $\dot{\psi}$ and output from the yaw rate sensor II₁ in the vehicle behavior sensor, the signals corresponding to the vehicle wheel angular velocities and output from the vehicle wheel angular velocity sensors VI_{1i} (i = 1, 2, 3, 4) and the signals corresponding to the vehicle wheel loads and output from the load sensors VI₁₂ (i = 1, 2, 3, 4) in addition to the signal corresponding to the steering control signal as an output from the adder/subtractor III₃, and the signal corresponding to the vehicle velocity u_0 .

30 The gain changing means III₄ estimates the yaw rate of the vehicle on the basis of the input signals, compares the estimated value with the peak value of the actual yaw rate to estimate μ , and calculates optimal gains corresponding to the current vehicle state on the basis of the estimated μ value and the vehicle velocity u_0 .

The calculated optimal gain values as the optimal gain outputs G_i (i = 1 to 6) from the output port 204 35 in the gain changing means III₄ are input to the first and second coefficient circuits III₁₂ and III₁₅ in the feed forward signal operating means III₁ and the four coefficient circuits III₂₁, III₂₃, III₂₆, and III₂₇ in the feedback signal operating means III₂. These optimal gains serve as those for the signals δ , $\dot{\delta}$, ψ , $\dot{\psi}$, \hat{y} , and \dot{y} , respectively.

40 The adder III₁₇ in the feed forward signal operating means III₁ adds a signal $G_1 \cdot \delta$ obtained by multiplying the steering angle signal δ with the optimal gain G_1 and a signal $G_2 \cdot \dot{\delta}$ obtained by multiplying the differential value signal $\dot{\delta}$ of the steering angle with the optimal gain G_2 and outputs a feed forward signal $\delta + G_1 \cdot \delta + G_2 \cdot \dot{\delta}$ to the control signal operating means III₃.

45 The adder III₂₅ in the feedback signal operating means III₂ adds a signal $G_3 \cdot \dot{\psi}$ obtained by multiplying the yaw rate signal $\dot{\psi}$ with the optimal gain G_3 , a signal $G_4 \cdot \hat{\psi}$ obtained by multiplying the pseudo yaw angle signal $\hat{\psi}$ with the optimal gain G_4 , a signal $G_5 \cdot \hat{y}$ obtained by multiplying the pseudo lateral velocity signal \hat{y} with the optimal gain G_5 , and a signal $G_6 \cdot \dot{y}$ obtained by multiplying the pseudo lateral displacement signal \dot{y} with the optimal gain G_6 and outputs a feedback signal $G_3 \cdot \dot{\psi} + G_4 \cdot \hat{\psi} + G_5 \cdot \hat{y} + G_6 \cdot \dot{y}$ to the control signal operating means III₃.

50 The driving means IV drives the actuator means V in accordance with the operation control signal δ_r from the control signal operating means III₃:

$$\delta_r = \delta + G_1 \cdot \delta + G_2 \cdot \dot{\delta} + G_3 \cdot \dot{\psi} + G_4 \cdot \hat{\psi} + G_5 \cdot \hat{y} + G_6 \cdot \dot{y}$$

55 The actuator means V drives the front wheel steering mechanism V_{10} to perform predetermined steering control.

The optimal front wheel steering control angles δ_r instantaneously detect the variables representing the vehicle and the vehicle behaviors and give the coefficients G_i according to the degrees of contribution, thereby constituting a feedback control system for controlling instantaneous states including the factors of

the driver. Therefore, optimal steering angle control can be performed for the vehicle driven by the driver. At the same time, the coefficients G_i ($i = 1, 2$ to 6) are determined by the estimated μ value during steady traveling and the slip ratio of each vehicle wheel and the vehicle velocity u_0 . In this case, the estimated μ value is determined such that the estimated value of the yaw rate generated on the smooth road is compared with the actual yaw rate. When the vehicle travels in an abnormal state, e.g., on a slippery road, an auxiliary steering angle can be added. Zig-zag traveling or a spin caused by slipping during straight driving free from the yaw rate can be prevented. When the driver does not notice changes in vehicle wheel and road surface conditions, or at the time of rapid start or stop, the dynamic characteristics of the vehicle can be automatically controlled, and optimal steering angle control corresponding to given weather and road conditions can be performed.

Fifth Embodiment

An apparatus for controlling steering of wheels of a vehicle according to a fifth embodiment which belongs to the eleventh, twelfth, thirteenth, and fourteenth modes of the present invention will be described in detail with reference to Figs. 35 and 36. Differences between the fifth and fourth embodiments are concentrated.

The apparatus of this embodiment is applied to an apparatus for controlling steering of front wheels of the vehicle. The apparatus belongs to the eleven mode shown in Fig. 4 and comprises a steering sensor I, a vehicle behavior sensor II, a control means III, a driving means IV, an actuator means V, and a vehicle state detection sensor VI.

The vehicle state detection sensor VI comprises a vehicle velocity sensor VI_0 , vehicle wheel angular velocity sensors VI_{i1} ($i = 1, 2, 3, 4$) for measuring the respective vehicle wheel angular velocities, load sensors VI_{i2} ($i = 1, 2, 3, 4$) for measuring the respective vehicle wheel loads, and road surface shape sensors VI_{i3} ($i = 1, 2, 3, 4$), as shown in Fig. 35.

The gain changing means III_4 comprises a microcomputer 200. The microcomputer 200 comprises: an input port 201 for receiving a signal corresponding to a yaw rate $\dot{\psi}$, a signal corresponding to a vehicle velocity u_0 , a signal corresponding to a steering control signal as an output from an adder/subtractor III_{31} , signals corresponding to the vehicle wheel angular velocities, signals corresponding to the vehicle wheel loads, and signals corresponding to the road surface shapes; an arithmetic and logic unit 202 for estimating vehicle behavior variables, a friction value μ between each wheel and the road surface, calculating a slip ratio of each vehicle wheel, and determining the road surface shapes and abnormalities of the sensors on the basis of the input signals, and for calculating optimal gains of the above operations; a memory 203 for storing vehicle specifications and the algorithm for and operation results of the arithmetic and logic unit 202, and an output port 204 for outputting the optimal gains selected from the arithmetic and logic unit 202.

The functions of the microcomputer 200 will be described in detail with reference to a flow chart in Fig. 36.

When the driver turns on the ignition key, the programs in the microcomputer 200 are started and initialization (P31) is performed. In initialization routine P31, hardware such as an A/D converter and a D/A converter and software such as control parameters are initialized.

When initialization routine P31 is completed, the microcomputer 200 receives the yaw rate $\dot{\psi}$ from the yaw rate sensor II_1 , the steering control signal as an output from the adder/subtractor III_{31} , the vehicle velocity u_0 from the sensor VI_0 , and the vehicle wheel angular velocity and load signals and road surface shape signals or signal like road surface shape (e.g., sprung relative displacements and velocities) through the A/D converter (P32).

When all signals are fetched in P32, the microcomputer 200 determines the road surface shapes on the basis of the outputs from the road surface shape sensors VI_{i3} ($i = 1, 2, 3, 4$) (P33). If the road surface is determined to be a rough road surface, the flow advances to program P39 without executing the following routine.

If the road surface is determined in P33 not to be a rough road surface, the microcomputer 200 determines whether output values from the steering angle sensor and the vehicle behavior sensor are abnormal (P34). In this case, the following operations are performed to determine: (i) whether the sensor output values exceed a predetermined value which is the upper limit for possible vehicle motion; and (ii) whether the sensor output values do not contradict with other conditions. If the above conditions are satisfied and the sensor outputs are determined to be abnormal, the flow advances to program P39 without executing the following routine.

The coefficients of vehicle yaw rate estimation model (8) (equations (7) and (8)) are calculated on the basis of the vehicle velocity u_0 , the vehicle wheel loads, and the vehicle specifications. The resultant coef-

ficient values and the steering control signal as an output from the adder/subtractor III₃₁, are used to solve equation (8) to obtain an estimated value $\dot{\psi}_m$ of the vehicle yaw rate (P35).

The corresponding signal change points (i.e., the peak values and peak phase values) of the yaw rate $\dot{\psi}$ input from the A/D converter and the estimated value $\dot{\psi}_m$ obtained in P35 are calculated (P36).

5 The friction value μ is estimated by the peak value obtained in P36 (P37). More specifically, if the peak value phase difference obtained in P36 exceeds a threshold value (e.g., 90°), the microcomputer 200 determines that the friction value μ is small and the flow advances to the next step. However, the peak value phase difference is smaller than the threshold value, a peak ratio $\dot{\psi}/\dot{\psi}_m$ is calculated. The coefficient of the μ estimation equation (16) is calculated by equations (7) and (13) using vehicle specifications and the vehicle velocity u_0 . The resultant coefficient value and the peak ratio are used to solve equation (16) to estimate μ .

The slip ratios are calculated using the vehicle velocity u_0 read in P32 and the respective vehicle wheel angular velocities (P38).

15 Optimal coefficients are selected for the estimated μ values estimated in P37, the slip ratios calculated in P38, the vehicle velocity u_0 , the rough road determination result, and the sensor abnormality determination result and are output to the coefficient circuits III₁₂, III₁₆, III₂₁, III₂₃, III₂₆, and III₂₇ (P39). Thereafter, the flow returns to P32.

The driving means IV, the actuator means V, and the vehicle velocity detection sensor VI₀ have the same arrangements as in the fourth embodiment.

20 The function and the effect of the fifth embodiment having the above arrangement will be described below.

The input port 201 in the gain changing means III₄ receives the signal corresponding to the yaw rate $\dot{\psi}$ and output from the yaw rate sensor II₁ in the vehicle behavior sensor II, the vehicle wheel angular velocity signals output from the vehicle wheel angular velocity sensors VI₁₁ ($i = 1, 2, 3, 4$), the vehicle wheel load signals output from the load sensors VI₁₂ ($i = 1, 2, 3, 4$), and the road surface shape signals from the road surface shape sensors VI₁₃ ($i = 1, 2, 3, 4$) in addition to the signal corresponding to the steering control signals as an output from the adder/subtractor III₃₁ and the signal corresponding to the vehicle velocity u_0 .

25 The gain changing means III₄ calculates optimal gains on the basis of the input signals in the same manner as in the third embodiment. The optimal gain outputs G_i ($i = 1$ to 6) appear at the output port 204 in the gain changing mean III₄ to the first and second coefficient circuits III₁₂ and III₁₆ in the feed forward signal operating means III₁ and the four coefficient circuits III₂₁, III₂₃, III₂₆, and III₂₇ in the feedback signal operating means III₂ and serve as those for the signals δ , $\dot{\delta}$, ψ , $\dot{\psi}$, $\ddot{\psi}$, and y , respectively.

30 Unlike the conventional control system drawback caused by using as feedback and feed forward signals the signals obtained by multiplying the signals for variables representing vehicle behaviors and the steering angle signals with coefficients after the road conditions and sensor operating states are detected, the following operation errors can be prevented according to the present invention. These errors occur as follows. The vehicle behavior detection sensor erroneously detects that vehicle vibrations are not caused by vehicle motion but by the bumps or the like of the road surface. However, the vibration detection signal is used as if it is generated by vehicle motion, and therefore, the detection signal is used for feed forward or feedback control. In addition, an abnormal signal generated by sensor failures or the like is used for feed forward or feedback control to cause the operation errors in the steering control system. The above drawbacks can be completely eliminated from the apparatus of this embodiment. In addition to the steering control effect of the fourth embodiment, the apparatus of the fifth embodiment can perform a safer and more reliable control operation.

Claims

- 45
1. An apparatus for controlling steering of wheels of a vehicle, comprising : a steering sensor (I) for detecting a steering angle of a steering wheel ;
 - 50 a vehicle behavior sensor (II) for detecting variables representing vehicle behaviors ;
 - control means (III) comprising feed forward signal operating means (III₁) provided with a steering angle signal circuit (III₁₁) for transmitting, without modifications, a steering angle signal output from said steering sensor, characterized in that there are provided further means as follows :
 - 55 a steering angle signal operating circuit (III₁₃) having a first coefficient circuit (III₁₂) for multiplying the steering angle signal with a coefficient,
 - a steering angular velocity signal operating circuit (III₁₆) having a differentiator (III₁₄) for calculating a steering angular velocity signal from the steering angle signal and a second coefficient circuit (III₁₅) for mul-

tipling the steering angular velocity signal with a coefficient, and an adder (III₁₇) for adding signals output from said steering angle signal circuit, said steering angle signal operating circuit, and said steering angular velocity signal operating circuit to output a sum signal, the sum signal being output as a feed forward signal, feedback signal operating means (III₂) provided with a vehicle behavior state variable signal operating circuit (III₂₂) having a third coefficient circuit (III₂₁) for multiplying with a coefficient the signals for variables representing vehicle behaviors and output from said vehicle behavior sensor, said vehicle behavior state variable signal operating circuit outputting a signal as a feedback signal, and

control signal operating means (III₃) provided with an adder/subtractor (III₃₁) for calculating a difference or a sum of signals output from said feed forward signal operating means and said feedback signal operating means and for outputting a steering control signal ;

driving means (IV) for amplifying a power of the steering control signal as an output from said control means ; and actuator means (V) for applying an optimal steering angle of either front or rear wheels or both on the basis of an output from said driving means.

2. An apparatus according to claim 1, further comprising a vehicle state detection sensor (VI) for detecting vehicle travel state variable with the vehicle travel, wherein said control means (III) comprises gain changing means (III₄), connected to said vehicle state detection sensor (VI) and said first coefficient circuit (III₁₂), for changing the coefficient of said first coefficient circuit (III₁₂) on the basis of the signals for vehicle travel state variable with the vehicle travel output from said vehicle state detection sensor (VI).

3. An apparatus according to claim 2, further comprising an outside environmental situation detection sensor (VII) for detecting state variables representing outside environmental situations, wherein said control means comprises gain changing means (III₄), connected to said vehicle state detection sensor (VI) and/or said outside environmental situation detection sensor (VII) and said first coefficient circuit (III₁₂) for changing the coefficient of said first coefficient circuit (III₁₂) on the basis of the signals for vehicle travel state variables with the vehicle travel and output from said vehicle state detection sensor (VI) and/or signals for state variables representing outside environmental situations and output from said outside environmental situation detection sensor (VII).

4. An apparatus according to claim 3, wherein said gain changing means (III₄) comprises gain changing means, connected to said first and second coefficient circuits (III₁₂, III₁₅) on the basis of the signals for vehicle travel state variable with the vehicle travel and output from said vehicle state detection sensor (VI) and/or the signals for state variables representing the outside environmental situations and output from said outside environmental situation detection sensor (VII).

5. An apparatus according to claim 4, wherein said gain changing means (III₄) comprises gain changing means, connected to said first, second, and third coefficient circuits (III₁₂, III₁₅, III₂₁), for changing the coefficients of said first, second, and third coefficient circuits on the basis of the signals for vehicle travel state variable with the vehicle travel and output from said vehicle state detection sensor (VI) and/or the signals for state variables representing the outside environmental situations and output from said outside environmental situation detection sensor (VII).

6. An apparatus according to claim 5, wherein said gain changing means (III₄) comprises gain changing means, connected to said vehicle state detection sensor (VI) and/or said outside environmental situation detection sensor (VII) and said steering sensor (I) and/or said steering angular velocity signal operating circuit (III₁₈), for changing the coefficient of at least one of said coefficient circuits (III₁₂, III₁₅, III₂₁) on the basis of signals for vehicle travel state variable with the vehicle travel and output from said vehicle state detection sensor (VI) and/or the signals for state variables representing the outside environmental situations and output from said outside environmental situation detection sensor (VII) and the steering angle signal from said steering sensor (I) and/or the steering angular velocity signal output from said steering angular velocity signal operating circuit (III₁₈).

7. An apparatus according to claim 5, wherein said gain changing means (III₄) comprises gain changing means, connected to said vehicle state detection sensor (VI) and/or said outside environmental situation sensor (VII), said steering sensor (I) and/or said steering angular velocity signal operating circuit (III₁₈), and said vehicle behavior sensor (II), for changing the coefficient of at least one of said coefficient circuits (III₁₂, III₁₅, III₂₁) on the basis of the signals for vehicle travel state variable with the vehicle travel and output from said vehicle state detection sensor (VI) and/or the signals for state variable representing outside environmental situations, the steering angle signal from said steering sensor (I) and/or the steering angular velocity signal from said steering angular velocity signal operating circuit (III₁₈), and the signals for variables representing the vehicle behaviors and output from said vehicle behavior sensor (II).

8. An apparatus according to claim 3 or 7, wherein said gain changing means (III₄) comprises :

sense-of-situation determining means (III₄₁) for determining a current level of a vehicle situation with reference to human senses on the basis of at least one of the signals for vehicle travel state variable with

the vehicle travel and output from said vehicle state detection sensor (VI), the signals for state variables representing the outside environmental situations and output from said outside environmental situation detection sensor (VII), the steering angle signal output from said steering sensor (I), the steering angular velocity signal output from said steering angular velocity signal circuit (III₁₆), and the signals for variables representing the vehicle behaviors and output from said vehicle behavior sensor (II) ;

vehicle state determining means (III₄₂) for determining necessity of stability and controllability by using functions for replacing outputs from said sense-of-situation determining means (III₄₁) into the necessity of stability and controllability ; and

gain deciding means (III₄₃) for deciding gains from output values from said vehicle state determining means (III₄₂) and outputting the gains to said coefficient circuits.

9. An apparatus according to claim 8, wherein said gain deciding means (III₄₃) in said gain changing means comprises :

a memory (III₄₄) for calculating gain values for optimizing vehicle motion in a state of the necessity of stability and controllability and for storing calculated results ; and

a gain selector (III₄₅) for selecting the gains by selecting the gain values calculated in the state of the necessity of stability and controllability from said memory (III₄₄), on the basis of the determination result from said vehicle state determining means (III₄₂).

10. An apparatus according to claim 8, wherein said gain deciding means (III₄₃) in said gain changing means comprises a memory (III₄₄) for storing a stability priority gain for increasing vehicle stability and a response priority gain for increasing the vehicle response, and a gain calculation section (III₄₆) for weighting these two gains on the basis of the determination value from said vehicle state determining means (III₄₂) and calculating gains suitable for the current situation.

11. An apparatus according to claim 2, wherein said gain changing means (III₄) comprises :

vehicle behavior state variable estimating means (III₄₁) for estimating the variables representing vehicle behaviors on the basis of the steering angle signal output from said steering sensor (I) and the signals for vehicle travel state variable with the vehicle travel and output from said vehicle state detection sensor (VI) ;

μ estimating means (III₄₂) for estimating a friction value (μ) between the vehicle wheels and the road surface on the basis of a vehicle behavior state variable estimating means (III₄₁) and the signals for variables representing the vehicle behaviors and output from said vehicle behavior sensor (II) ; and coefficient circuit coefficient changing means (III₄₃) for changing the coefficient of at least one of said first, second, and third coefficient circuits (III₁₂, III₁₆, III₂₁) on the basis of an estimated μ signal output from said μ estimating means (III₄₂), an optimal gain being supplied to said at least one of said first, second, and third coefficient circuits.

12. An apparatus according to claim 2, wherein said gain changing means (III₄) comprises : means (III₄₁) for estimating the variables representing the vehicle behaviors on the basis of the steering control signal output from said control signal operating means (III₃) and the signals for vehicle travel state and output from said vehicle state detection sensor (VI) ;

μ estimating means (III₄₂) for estimating a friction value on the basis of the signals for estimating the state variables being output from said state variable estimating means (III₄₁) and the signals for variables representing vehicle behaviors and output from said vehicle behavior sensor (II) ;

slip ratio calculating means (III₄₄) for calculating slip ratios of the vehicle wheels on the basis of the signals for vehicle travel state and output from said vehicle state detection sensor (VI) and vehicle wheel velocities,

road surface shape estimating means (III₄₅) for estimating road surface shapes on the basis of the signals for vehicle travel variables with the vehicle travel and output from said vehicle state detection sensor (VI), and/or the sensor abnormality detecting means (III₄₆) for detecting abnormalities of said steering sensor (I), said vehicle behavior sensor (II), and said vehicle state detection sensor (VI) ; and

coefficient circuit coefficient changing means (III₄₃) for changing the coefficient of at least one of said first, second, and third coefficient circuits (III₁₂, III₁₆, III₂₁) on the basis of an estimated μ signal output from said μ estimating means (III₄₂), and said slip ratio signals, said road surface shape signals and/or said sensor abnormality detection signals.

Ansprüche

1. Steuervorrichtung für das Lenken der Räder eines Fahrzeugs, mit einem Lenksensor (I) zum Detektieren eines Lenkwinkels eines Lenkrades, mit einem Sensor (II) für das Verhalten des Fahrzeugs zum Detektieren von Variablen, welche das Verhalten des Fahrzeugs wiedergeben, mit Steuermitteln (III), wel-

che eine Mitkopplungssignal-Operationseinrichtung (III₁) umfassen, die mit einer Lenkwinkel-Signalabeschaltung (III₁₁) ausgestattet ist, um ohne Veränderungen ein Lenkwinkelsignal zu übertragen, welches von dem Lenk-Sensor ausgegeben wird, dadurch gekennzeichnet, daß die folgenden weiteren Einrichtungen vorgesehen sind:

- 5 eine Lenkwinkelsignal-Operationsschaltung (III₁₃) mit einer ersten Koeffizientenschaltung (III₁₂) zum Multiplizieren des Lenkwinkelsignals mit einem Koeffizienten, eine Lenkwinkel-Geschwindigkeitssignal-Operationsschaltung (III₁₆) mit einer Differenzierschaltung (III₁₄) zum Berechnen eines Lenkwinkel-Geschwindigkeitssignals aus dem Lenkwinkelsignal und mit einer zweiten Koeffizientenschaltung (III₁₅) zum Multiplizieren des Lenkwinkel-Geschwindigkeitssignals mit einem Koeffizienten und eine Addierstufe (III₁₇) zum Addieren der Signale, die von der Lenkwinkelsignalschaltung, der Lenkwinkelsignal-Operationschaltung und der Lenkwinkel-Geschwindigkeitssignal-Operationsschaltung abgegeben wurden, um ein Summensignal abzugeben, wobei das Summensignal als ein Mitkopplungssignal ausgegeben wird, eine Rückkopplungssignal-Operationseinrichtung (III₂), die mit einer Operationsschaltung (III₂₂) für ein den Zustand des Fahrzeugverhaltens angegebendes variables Signal ausgestattet ist, welche eine dritte Koeffizientenschaltung (III₂₁) enthält, um die Signale für die Variablen mit einem Koeffizienten zu multiplizieren, welche die verschiedenen Fahrzeugsverhalten wiedergeben und von dem Sensor für das Fahrzeugverhalten ausgegeben werden, wobei die Operationsschaltung für das variable Signal entsprechend dem Zustand des Fahrzeugverhaltens ein Signal als Rückkopplungssignal ausgibt, und eine Steuersignal-Operationseinrichtung (III₃), die mit einem Addierer/Subtrahierer (III₃₁) ausgestattet ist, um eine Differenz oder eine Summe der Signale zu berechnen, die von der Operationseinrichtung für das Mitkopplungssignal und die Operationseinrichtung für das Rückkopplungssignal ausgegeben wurden und um ein Lenksteuersignal auszugeben, eine Treibereinrichtung (IV) zum Verstärken der Energie des Lenksteuersignals in Form einer Ausgangsgröße der Steuereinrichtung, und eine Betätigungseinrichtung (V), um einen optimalen Lenkwinkel für entweder die Vorderräder oder die Heckräder oder für beide auf der Grundlage der Ausgangsgröße der Treibereinrichtung einzustellen.

2. Steuervorrichtung nach Anspruch 1, gekennzeichnet durch einen den Fahrzeugzustand feststellenden Sensor (VI) zum Detektieren einer Variablen entsprechend dem Fahrzustand des Fahrzeugs, wenn das Fahrzeug fährt, wobei die Steuereinrichtung (III) eine Einrichtung (III₄) zur Veränderung der Verstärkung enthält, die mit dem Sensor (VI) für die Feststellung des Fahrzeugzustandes und der ersten Koeffizientenschaltung (III₁₂) verbunden ist, um den Koeffizienten der ersten Koeffizientenschaltung (III₁₂) auf der Grundlage der Signale für den Fahrzeugfahrzustand zu verändern, die sich bei fahrendem Fahrzeug entsprechend der Ausgangsgröße des Sensors (VI) für die Feststellung des Fahrzeugzustands verändern.

3. Steuervorrichtung nach Anspruch 2, dadurch gekennzeichnet, daß ein Sensor (VII) für die Feststellung der äußeren Umgebungsbedingung vorgesehen ist, um Zustandsvariable, welche die äußeren Umgebungssituationen wiedergeben, zu detektieren, wobei die Steuereinrichtung Mittel (III₄) zur Veränderung der Verstärkung enthält, die mit dem Sensor (VI) zum Detektieren des Fahrzeugzustands verbunden sind und/oder mit dem Sensor (VII) zum Detektieren der äußeren Umgebungssituation und der ersten Koeffizientenschaltung (III₁₂) verbunden sind, um den Koeffizienten der ersten Koeffizientenschaltung (III₁₂) auf der Grundlage der Signale für die Fahrzeugfahrzustands-Variablen bei fahrendem Fahrzeug zu verändern und welche von dem Fahrzeugzustands-Sensor (VI) ausgegeben werden und/oder auf der Grundlage der Signale für die Zustandsvariablen, welche äußere Umgebungssituationen wiedergeben und von dem Sensor (VII) zum Feststellen der äußeren Umgebungssituation ausgegeben werden.

4. Steuervorrichtung nach Anspruch 3, dadurch gekennzeichnet, daß die Mittel (III₄) zur Veränderung der Verstärkung eine Verstärkungsänderungseinrichtung umfassen, die mit der ersten und der zweiten Koeffizientenschaltung (III₁₂, III₁₅) auf der Grundlage der Signale für die Fahrzeugfahrzustands-Variable bei fahrendem Fahrzeug verbunden ist und welche von dem Sensor (VI) für die Feststellung des Fahrzeugzustands ausgegeben werden und/oder auf der Grundlage der Signale für die Zustandsvariablen, welche die äußeren Umgebungssituationen wiedergeben und von dem Sensor (VII) für die äußere Umgebungssituation abgegeben werden.

5. Steuervorrichtung nach Anspruch 4, dadurch gekennzeichnet, daß die Mittel (III₄) zur Änderung der Verstärkung eine Verstärkungsänderungseinrichtung umfassen, die mit der ersten, zweiten und dritten Koeffizientenschaltung (III₁₂, III₁₅, III₂₁) verbunden sind, um die Koeffizienten der ersten, zweiten und dritten Koeffizientenschaltung auf der Grundlage der Signale für die Fahrzeugfahrzustands-Variable bei fahrendem Fahrzeug zu ändern, die von dem Sensor (VI) für den Fahrzeugzustand ausgegeben werden und/oder auf der Grundlage der Signale für die Zustandsvariablen, welche die äußeren Umgebungssituationen bzw. Bedingungen wiedergeben und von dem Sensor (VII) für die äußere Umgebungsbedingung ausgegeben werden.

6. Steuervorrichtung nach Anspruch 5, dadurch gekennzeichnet, daß die Mittel (III₄) zur Änderung der

Verstärkung eine Verstärkungsänderungsvorrichtung umfassen, die mit dem Sensor (VI) für die Feststellung des Fahrzeugzustands und/oder dem Sensor (VII) zur Feststellung der äußeren Umgebungsbedingung und/oder der Lenkwinkelgeschwindigkeitssignal-Operationsschaltung (III₁₆) verbunden ist, um den Koeffizienten von wenigstens einer der Koeffizientenschaltungen (III₁₂, III₁₆, III₂₁) auf der Grundlage der Signale für die Fahrzeugzustands-Variablen bei fahrendem Fahrzeug zu ändern, die von dem Sensor (VI) für die Feststellung des Fahrzeugzustands ausgegeben werden und/oder auf der Grundlage der Signale für die Zustandsvariablen, welche die äußeren Umgebungsbedingungen wiedergeben und von dem Sensor (VII) für die Feststellung der äußeren Umgebungsbedingung ausgegeben wurden und auf der Grundlage des Lenkwinkelsignals des Lenksensors (I) und/oder des Lenkwinkel-Geschwindigkeitssignals, welches von der Lenkwinkelgeschwindigkeitssignal-Operationsschaltung (III₁₆) ausgegeben wurde.

7. Steuervorrichtung nach Anspruch 5, dadurch gekennzeichnet, daß die Mittel (III₄) zur Änderung der Verstärkung eine Verstärkungsänderungsvorrichtung umfassen, die mit dem Sensor (VI) für die Feststellung des Fahrzeugzustands und/oder dem Sensor (VII) für die Feststellung der äußeren Umgebungsbedingung, dem Lenksensor (I) und/oder der Lenkwinkelgeschwindigkeitssignal-Operationsschaltung (III₁₆) und dem Sensor (II) für das Fahrzeugverhalten verbunden ist, um den Koeffizienten von wenigstens einer der Koeffizientenschaltungen (III₁₂, III₁₆, III₂₁) auf der Grundlage der Signale für den Fahrzeugzustand zu verändern, die mit der Fahrt des Fahrzeugs veränderlich sind und von dem Sensor (VI) für die Feststellung des Fahrzeugzustands ausgegeben werden und/oder auf der Grundlage der Signale für die Zustandsvariable, welche die äußeren Umgebungsbedingungen wiedergeben, des Lenkwinkelsignals des Lenk-Sensors (I) und/oder des Lenkwinkel-Geschwindigkeitssignals von der Lenkwinkelgeschwindigkeitssignal-Operationsschaltung (III₁₆) und den Signalen für die Variablen, welche das Fahrzeugverhalten wiedergeben und von dem Sensor (II) für das Fahrzeugverhalten ausgegeben werden.

8. Steuervorrichtung nach Anspruch 3 oder 7, dadurch gekennzeichnet, daß die Mittel (III₄) zur Änderung der Verstärkung folgendes enthalten :

eine Einrichtung (III₄₁) zum Bestimmen der Feststellung einer Situation oder Bedingung zur Bestimmung eines laufenden Wertes einer Fahrzeugbedingung oder Situation unter Bezugnahme auf menschliche Wahrnehmungen auf der Grundlage des letzten einen Signals für den Fahrzeugzustand, welcher sich mit der Fahrt des Fahrzeugs verändert und von dem Sensor (VI) für die Feststellung des Fahrzeugzustands ausgegeben wurde, auf der Grundlage der Signale für die Zustandsvariablen, welche die äußeren Umgebungsbedingungen und Situationen wiedergeben und von dem Sensor (VII) für die Feststellung der äußeren Umgebungsbedingung ausgegeben wurden, auf der Grundlage des Lenkwinkelsignals, welches von dem Lenksensor (I) abgegeben wurde, des Lenkwinkelgeschwindigkeitssignals, welches von der Lenkwinkelgeschwindigkeitssignalschaltung (III₁₆) ausgegeben wurde, und auf der Grundlage der Signale für die Variablen, welche die Fahrzeugverhaltensweisen wiedergeben und von dem Sensor (II) für die Feststellung der Fahrzeugverhaltensweise ausgegeben wurden, eine den Fahrzeugzustand bestimmende Einrichtung (III₄₂) zum Bestimmen der Notwendigkeit einer Stabilität und Steuerbarkeit unter Verwendung von Funktionen zum Ersetzen von Ausgangsgrößen aus der Einrichtung (III₄₁) zum Bestimmen der Situationserfassung mit solchen der Notwendigkeit der Stabilität und der Steuerbarkeit, und eine Verstärkungsbestimmungseinrichtung (III₄₃) zum Bestimmen von Verstärkungswerten für die Ausgangswerte der Fahrzeugzustand-Bestimmungseinrichtung (III₄₂) und zum Ausgeben der Verstärkungswerte an die Koeffizientenschaltungen.

9. Steuervorrichtung nach Anspruch 8, dadurch gekennzeichnet, daß die Verstärkungsbestimmungseinrichtung (III₄₃) in der Verstärkungsänderungseinrichtung folgendes enthält :

eine Speichereinrichtung (III₄₄) zum Berechnen von Verstärkungswerten zur Optimierung der Fahrzeugbewegung in einem Zustand der Notwendigkeit der Stabilität und der Steuerbarkeit und zum Speichern der berechneten Ergebnisse, und einen Verstärkungswähler (III₄₅) zum Auswählen der Verstärkungen durch Auswählen der Verstärkungswerte aus der Speichereinrichtung (III₄₄), die im Zustand der Notwendigkeit der Stabilität und Steuerbarkeit berechnet wurden, auf der Grundlage des Bestimmungsergebnisses der Fahrzeugzustand-Bestimmungseinrichtung (III₄₂).

10. Steuervorrichtung nach Anspruch 8, dadurch gekennzeichnet, daß die Verstärkungs-Bestimmungseinrichtung (III₄₃) in der Verstärkungsänderungseinrichtung einen Speicher (III₄₄) zum Speichern einer Stabilitäts-Prioritätsverstärkung enthält, um die Fahrzeugstabilität zu erhöhen und um eine Ansprech-Prioritätsverstärkung zum Erhöhen des Fahrzeugansprechverhaltens zu speichern, und einen Verstärkungsberechnungsabschnitt (III₄₆) enthält, um die zwei Verstärkungswerte auf der Grundlage des Bestimmungswertes der Fahrzeugzustand-Bestimmungseinrichtung (III₄₂) zu wichten und um Verstärkungswerte zu berechnen, die für die laufende Situation geeignet sind.

11. Steuervorrichtung nach Anspruch 2, dadurch gekennzeichnet, daß die Verstärkungsänderungseinrichtung (III₄) folgendes enthält : eine Schätzeinrichtung (III₄₁) für den variablen Fahrzeugverhaltenszustand zum Schätzen der Variablen, welche die Fahrzeugverhaltensweisen wiedergeben, und zwar auf der

Grundlage des Lenkwinkelsignals, welches von dem Lenksensor (I) ausgegeben wurde, und auf der Grundlage der Signale für den Fahrzeugfahrzustand, die mit der Fahrt des Fahrzeugs variabel sind und von dem Sensor (VI) für die Erfassung des Fahrzeugzustands ausgegeben wurden, eine μ -Schätzeinrichtung (III₄₂) zum Schätzen eines Reibungsbeiwertes (μ) zwischen den Fahrzeugrädern und der Straßenoberfläche unter Verwendung der Schätzeinrichtung (III₄₁) für den variablen Fahrzeugverhaltenszustand und auf der Grundlage der Signale für die Variablen, welche die Fahrzeugverhaltensweisen wiedergeben und von dem Sensor (II) für das Fahrzeugverhalten ausgegeben wurden, und eine Koeffizientenänderungseinrichtung (III₄₃) für die Koeffizientenschaltung zum Ändern des Koeffizienten von wenigstens einer der ersten, zweiten und dritten Koeffizientenschaltungen (III₁₂, III₁₅, III₂₁) auf der Grundlage eines geschätzten μ -Signals, welches von der μ -Schätzeinrichtung (III₄₂) ausgegeben wurde, wobei ein optimaler Verstärkungswert zu der genannten wenigstens einen ersten, zweiten und dritten Koeffizientenschaltung übertragen wird.

12. Steuervorrichtung nach Anspruch 2, dadurch gekennzeichnet, daß die Verstärkungsänderungseinrichtung (III₄) folgendes enthält: Mittel (III₄₁) zum Schätzen der Variablen, welche die Fahrzeugverhaltensweisen wiedergeben, auf der Grundlage des Lenksteuersignals, welches von der Steuersignal-Operationseinrichtung (III₃) ausgegeben wurde und auf der Grundlage der Signale für den Fahrzeugfahrzustand, die von dem Sensor (VI) für die Feststellung des Fahrzeugzustands ausgegeben wurden, eine μ -Schätzeinrichtung (III₄₂) zum Schätzen eines Reibungsbeiwertes auf der Grundlage der Signale zum Schätzen der Zustandsvariablen, die von der Schätzeinrichtung (III₄₁) für die Zustandsvariable ausgegeben wurden und auf der Grundlage der Signale für die Variablen, welche die Fahrzeugverhaltensweisen wiedergeben und von dem Sensor (II) für das Fahrzeugverhalten ausgegeben wurden, eine Schlupfverhältnis-Berechnungseinrichtung (III₄₄) zum Berechnen der Schlupfverhältnisse der Fahrzeugräder auf der Grundlage der Signale für den Fahrzeugfahrzustand, die von dem Sensor (VI) für die Feststellung des Fahrzeugzustands ausgegeben wurden und auf der Grundlage der Raddrehzahlen des Fahrzeugs, eine Schätzeinrichtung (III₄₅) für die Straßenoberflächengestalt, um Straßenoberflächengestalten auf der Grundlage der Signale für die Fahrzeugfahr-Variablen bei fahrendem Fahrzeug zu schätzen, die von dem Sensor (VI) für die Feststellung des Fahrzeugzustands ausgegeben wurden und/oder eine Detektoreinrichtung (III₄₆) für eine Sensor-Regelwidrigkeit, um Abweichungen oder Regelwidrigkeiten des Lenksensors (I), des Sensors (II) für das Fahrzeugverhalten und des Sensors (VI) für die Feststellung des Fahrzeugzustands festzustellen, und eine Koeffizientenänderungseinrichtung (III₄₃) für die Koeffizientenschaltung, um den Koeffizienten von wenigstens einer der ersten, zweiten und dritten Koeffizientenschaltung (III₁₂, III₁₅, III₂₁) auf der Grundlage eines geschätzten μ -Signals, welches von der μ -Schätzeinrichtung (III₄₂) abgegeben wurde, der Schlupfverhältnissignale, der Straßenoberflächengestalt-Signale und/oder der Sensorregelwidrigkeit-Feststellungssignale zu ändern.

Revendications

1. Dispositif de commande du braquage des roues d'un véhicule comprenant :
 - un capteur de braquage (I) pour détecter l'angle de braquage d'un volant de braquage ;
 - un capteur de comportement du véhicule (II) pour détecter des variables représentant des comportements du véhicule ;
 - des moyens de commande (III) comprenant des moyens d'exploitation d'un signal d'action (III₁) munis d'un circuit de signal d'angle de braquage (III₁₁) pour transmettre, sans modification, un signal d'angle de braquage issu dudit capteur de braquage, caractérisé en ce que les moyens supplémentaires suivants sont prévus :
 - un circuit d'exploitation du signal d'angle de braquage (III₁₃), comportant un premier circuit de facteur (III₁₂) pour multiplier le signal d'angle de braquage par un certain facteur ;
 - un circuit d'exploitation d'un signal de vitesse angulaire de braquage (III₁₆), comportant un différentiateur (III₁₄) pour calculer un signal de vitesse angulaire de braquage à partir du signal d'angle de braquage, et un second circuit de facteur (III₁₅) pour multiplier le signal de vitesse angulaire de braquage par un certain facteur, et un additionneur (III₁₇) pour additionner les signaux issus du circuit de signal d'angle de braquage, du circuit d'exploitation du signal d'angle de braquage, et du circuit d'exploitation du signal de vitesse angulaire de braquage, pour produire un signal somme, le signal somme étant produit comme signal d'action, des moyens d'exploitation d'un signal de rétroaction (III₂) munis d'un circuit d'exploitation (III₂₂) du signal de variable d'état de comportement du véhicule, comportant un troisième circuit de facteur (III₂₁) pour multiplier par un certain facteur les signaux correspondant aux variables représentant des comportements du véhicule et issus dudit capteur de comportement du véhicule, ce circuit d'exploitation du signal de variable d'état de comportement du véhicule produisant un signal comme signal de rétroaction ; et

– des moyens d'exploitation du signal de commande (III₃) munis d'un additionneur/soustracteur (III₃₁) pour calculer une différence ou une somme de signaux issus des moyens d'exploitation du signal d'action et des moyens d'exploitation du signal de rétroaction, et pour produire un signal de commande de braquage;

– des moyens d'attaque (IV) pour amplifier la puissance du signal de commande de braquage comme sorti desdits moyens de commande, et des moyens d'actionnement (V) pour appliquer un angle de braquage optimum des roues avant ou arrière ou des deux, sur la base d'une sortie desdits moyens d'attaque.

2. Dispositif conforme à la revendication 1, comprenant de plus un capteur de détection de l'état du véhicule (VI) pour détecter l'état de déplacement du véhicule, variable avec le déplacement du véhicule, dans lequel lesdits moyens de commande (III) comprennent des moyens de changement du gain (III₄), reliés au capteur de détection de l'état du véhicule (VI) et audit premier circuit de facteur (III₁₂) pour changer le facteur dudit premier circuit de facteur (III₁₂) sur la base des signaux d'état de déplacement du véhicule, variables avec le déplacement du véhicule, issus dudit capteur de détection de l'état du véhicule (VI).

3. Dispositif conforme à la revendication 2, comprenant de plus un capteur de détection (VII) de la situation de l'environnement extérieur pour détecter les variables d'état représentant les situations de l'environnement extérieur, dans lequel lesdits moyens de commande comprennent des moyens de changement du gain (III₄), reliés au capteur de détection de l'état du véhicule (VI) et/ou au capteur de détection (VII) de la situation de l'environnement extérieur et au circuit de premier facteur (III₁₂) pour changer le facteur dudit circuit de premier facteur (III₁₂) sur la base des signaux d'état de déplacement du véhicule, variables avec le déplacement du véhicule et issus dudit capteur (VI) de détection de l'état du véhicule et/ou des signaux de variables d'état représentant les situations d'environnement extérieur et issus dudit capteur de détection (VII) de la situation de l'environnement extérieur.

4. Dispositif conforme à la revendication 3, dans lequel les moyens (III₄) de changement du gain comprennent des moyens de changement du gain, reliés auxdits premier et second circuits de facteur (III₁₂ III₁₅), sur la base des signaux d'état de déplacement du véhicule, variables avec le déplacement du véhicule et issus dudit capteur (VI) de détection de l'état du véhicule, et/ou des signaux des variables d'état représentant les situations d'environnement extérieur et issus dudit capteur de détection (VII) de la situation de l'environnement extérieur.

5. Dispositif conforme à la revendication 4, dans lequel les moyens (III₄) de changement du gain comprennent des moyens de changement du gain reliés auxdits premier, second et troisième circuits de facteur (III₁₂ III₁₅ III₂₁) pour changer les facteurs desdits premier, second et troisième circuits de facteur, sur la base des signaux d'état de déplacement du véhicule, variables avec le déplacement du véhicule et issus dudit capteur (VI) de détection de l'état du véhicule, et/ou des signaux des variables d'état représentant les situations d'environnement extérieur et issus dudit capteur de détection (VII) de la situation de l'environnement extérieur.

6. Dispositif conforme à la revendication 5, dans lequel les moyens (III₄) de changement du gain comprennent des moyens de changement du gain reliés au capteur (VI) de détection de l'état du véhicule, et/ou au capteur (VII) de détection de la situation de l'environnement extérieur et au capteur de braquage (I) et/ou au circuit (III₁₆) d'exploitation du signal de vitesse angulaire de braquage pour changer le facteur d'au moins l'un des circuits de facteur (III₁₂ III₁₅ III₂₁) sur la base des signaux d'état de déplacement du véhicule, variables avec le déplacement du véhicule et issus dudit capteur (VI) de détection de l'état du véhicule, et/ou des signaux des variables d'état représentant les situations d'environnement extérieur et issus dudit capteur de détection (VII) de l'état de l'environnement extérieur, et du signal d'angle de braquage issu du capteur de braquage (I), et/ou du signal de vitesse angulaire de braquage issu du circuit d'exploitation (III₁₆) du signal de vitesse angulaire de braquage.

7. Dispositif conforme à la revendication 5, dans lequel les moyens (III₄) de changement du gain comprennent des moyens de changement du gain reliés au capteur (VI) de détection de l'état du véhicule, et/ou au capteur (VII) de situation de l'environnement extérieur, au capteur de braquage (I) et/ou au circuit (III₁₆) d'exploitation du signal de vitesse angulaire de braquage et au capteur de comportement du véhicule (II) pour changer le facteur d'au moins l'un des circuits de facteur (III₁₂ III₁₅ III₂₁) sur la base des signaux d'état de déplacement du véhicule, variables avec le déplacement du véhicule et issus dudit capteur (VI) de détection de l'état du véhicule, et/ou des signaux des variables d'état représentant les situations d'environnement extérieur, du signal d'angle de braquage issu du capteur de braquage (I), et/ou du signal de vitesse angulaire de braquage issu du circuit d'exploitation (III₁₆) du signal de vitesse angulaire de braquage, et des signaux de variables représentant les comportements du véhicule et issus dudit capteur (II) de comportement du véhicule.

8. Dispositif conforme à l'une des revendications 3 ou 7, dans lequel les moyens (III₄) de changement du gain comprennent :

– des moyens (III₄₁) de détermination du sens de la situation, pour déterminer un état actuel de la situa-

- tion d'un véhicule par référence aux sens humains, sur la base d'au moins l'un des signaux d'état de déplacement du véhicule, variables avec le déplacement du véhicule et issus dudit capteur de détection de l'état du véhicule (VI), des signaux des variables d'état représentant les situations d'environnement extérieur et issus dudit capteur de détection (VII) de la situation de l'environnement extérieur, du signal d'angle de braquage issu dudit capteur de braquage (I), du signal de vitesse angulaire de braquage issu du circuit (III_{1a}) du signal de vitesse angulaire de braquage, et des signaux des variables représentant les comportements du véhicule et issus dudit capteur de comportement du véhicule (II) ;
- des moyens de détermination de l'état du véhicule (III₄₂) pour déterminer la nécessité de stabilisation et de commande en utilisant des fonctions pour remplacer les sorties des moyens de détermination du sens de la situation (III₄₁) s'il y a nécessité de stabilisation et de commande ; et
 - des moyens de choix du gain (III₄₃), pour choisir les gains des valeurs de sortie desdits moyens (III₄₂) de détermination de l'état du véhicule, et sortir les gains vers lesdits circuits de facteur.
9. Dispositif conforme à la revendication 8, dans lequel les moyens (III₄₃) de choix du gain dans les moyens de changement du gain comprennent :
- une mémoire (III₄₄) pour calculer les valeurs de gain pour l'optimisation du mouvement du véhicule dans un état de nécessité de stabilisation et de commande, et pour mettre en mémoire les résultats calculés ; et
 - un sélecteur de gains (III₄₅) pour choisir les gains en sélectionnant les valeurs de gains calculées dans l'état de nécessité de stabilisation et de commande, à partir de la mémoire (III₄₄), sur la base du résultat de la détermination par les moyens (III₄₂) de détermination de l'état du véhicule.
10. Dispositif conforme à la revendication 8, dans lequel les moyens (III₄₃) de choix du gain dans les moyens de changement du gain comprennent une mémoire (III₄₄) pour stocker un gain de stabilité prioritaire pour augmenter la stabilité du véhicule, et un gain de réponse prioritaire pour augmenter la réponse du véhicule, et une section de calcul du gain (III₄₆) pour pondérer ces deux gains sur la base de la valeur déterminée par les moyens de détermination de l'état du véhicule (III₄₂) et calculer les gains adaptés à la situation actuelle.
11. Dispositif conforme à la revendication 2, dans lequel les moyens de changement du gain (III₄) comprennent :
- des moyens d'estimation (III₄₁) des variables d'état de comportement du véhicule, pour estimer les variables représentant les comportements du véhicule sur la base du signal d'angle de braquage issu dudit capteur de braquage (I) et des signaux d'état de déplacement du véhicule, variables avec le déplacement du véhicule et issus dudit capteur (VI) de détection de l'état du véhicule ;
 - des moyens d'estimation de μ (III₄₂) pour estimer une valeur (μ) du frottement entre les roues du véhicule et la surface de la route, sur la base des moyens d'estimation d'une variable d'état du comportement du véhicule (III₄₁) et des signaux des variables représentant les comportements du véhicule, issus du capteur de comportement du véhicule (II) ; et des moyens (III₄₃) de changement du facteur du circuit de facteur, pour changer le facteur d'au moins l'un desdits premier, second et troisième circuits de facteur (III₁₂, III₁₅, III₂₁), sur la base d'un signal μ estimé issu des moyens (III₄₂) d'estimation de μ , un gain optimum étant fourni au moins audit premier, second ou troisième circuit de facteur.
12. Dispositif conforme à la revendication 2, dans lequel les moyens de changement du gain (III₄) comprennent :
- des moyens (III₄₁) pour estimer les variables représentant les comportements du véhicule sur la base du signal de commande de braquage issu des moyens (III₃) d'exploitation du signal de commande, et des signaux d'état de déplacement du véhicule, issus dudit capteur de détection de l'état du véhicule (VI) ;
 - des moyens d'estimation de μ (III₄₂) pour estimer une valeur de frottement sur la base des signaux d'estimation des variables d'état issus desdits moyens (III₄₁) d'estimation de la variable d'état et des signaux des variables représentant les comportements du véhicule et issus dudit capteur (II) de comportement du véhicule ;
 - des moyens de calcul du coefficient de glissement (III₄₄) pour calculer les coefficients de glissement des roues du véhicule sur la base des signaux représentant l'état de déplacement du véhicule et issus dudit capteur de détection de l'état du véhicule (VI), et des vitesses des roues du véhicule ;
 - des moyens d'estimation de la forme de la surface de la route (III₄₅) pour estimer les formes de la surface de la route, sur la base des signaux de déplacement du véhicule, variables avec le déplacement du véhicule et issus dudit capteur de détection de l'état du véhicule (VI), et/ou des moyens (III₄₆) de détection des anomalies des capteurs, pour détecter les anomalies dudit capteur de braquage (I), dudit capteur de comportement du véhicule (II), et dudit capteur de détection de l'état du véhicule (VI) ; et
 - des moyens de changement (III₄₃) du facteur du circuit de facteur, pour changer le facteur d'au moins l'un desdits premier, second et troisième circuits de facteur (III₁₂, III₁₅, III₂₁), sur la base d'un signal μ estimé

sortant des moyens (II₄₂) d'estimation de μ , et desdits signaux de coefficient de glissement, desdits signaux de forme de la surface de la route, et/ou desdits signaux de détection des anomalies des capteurs.
